Telegraphic Jubilee in Belgium.—The 9th of next month will mark the completion of the fiftieth anniversary of the introduction of telegraphy into Belgium, and the Postal Department is preparing to celebrate the event in a suitable fashion. In 1851 the total number of messages transmitted was 19,600 and the receipts £3,520. For the year 1894 the respective figures show a total of over 8,300,000 messages and £140,000.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

SCIENTIFIC EDUCATION.

The rapid advance of scientific knowledge during the last twenty-five years has changed nearly all processes of manufacture. Thus the nation which keeps its workers most to the front in the advance of knowledge gains a great advantage in this competitive age. Germany is fast becoming our most keen competitor in the manufacturing world, and a comparison between their system of scientific education and our own is of great interest. We are, therefore, pleased to give space in our columns to a long letter from Prof. W. Ostwald on this subject. This was addressed to Prof. Ramsay, and deal chiefly with his special subject, which is chemistry. In publishing the letter, Prof. Ramsay says that it shows that "our German competitors are straining every nerve to be first in the field with the enormous changes in chemical manufactures consequent on the application of the electric current to chemical operations. The far-sighted leaders of German industry, it will be seen from Prof. Ostwald's letter, are convinced that progress in pure science is progress in its industrial application, and Prof. Ostwald shows how the training which is deemed requisite and sufficient in Germany is given to students of chemistry. The chief lesson for us English to be learned from this letter is, he thinks, first, what a small part the examinational system plays in German methods of instruction; and, second, what a close bond exists between the man of pure science and the man interested in its industrial application. Our teachers, as well as our leaders in industry, may both with advantage profit by the lesson." On carefully reading the letter in question one cannot but admit that the German system is likely to produce good chemical experts. Also the study of chemistry, and especially of organic chemistry, is one which cannot be adequately given under an examination system. In fact, we think that this branch of science is peculiarly fitted to bring out good results with the German system of education. The close relationship between the scientific teachers of chemistry and the trade that exists in Germany is also found in England. A reference to the life of prominent members of the Iron and Steel Institute, for instance, will show what a large number owe their present position to their early training in chemistry. This knowledge has, however, been obtained at colleges where the examination has not been so strongly in evidence, and where opportunities for original work are provided. The chief difference between the educational systems of the two countries lies in the great difference in the routine adopted. In England the youth intending to follow a technical calling usually commences as a pupil in works at a comparatively early age—say, seventeen. Thus his technical and scientific education is acquired by study of an evening. The great aim of our examination system has been to cheapen the cost of this evening education to the pupil so that a workman's son can afford to attend. This payment by results tends, of course, to restrict the course to the rigid requirements of a syllabus, but with the

Digitized by Google

right men as teachers and a practical man as examiner a useful knowledge is given. As a rule, the teachers at these evening classes are also engaged in practical work in the subjects in which they give instruction. As a consequence, the apprentice or pupil can always raise points on subjects on which he finds he wants knowledge in his daily work. The higher technical education is now being provided for by the technical institutes springing up all over the country, where a day course will extend the information previously acquired. In engineering matters, we believe that the simultaneous progress in actual practice and theory is the best way of educating the average youth. In Germany, on the other hand, it is the exception for a man to commence practical work before he is twenty-two, and some take much longer over their education. This system is, as mentioned above, likely to turn out expert chemists, but we doubt that it is as good for the general engineer or for the electrical man. The professors at these schools are, as a rule, chosen because they distinguished themselves when obtaining their degrees, and they then never get into real touch with practical work. The instruction given by these gentlemen tends as a consequence to pure physics, with perhaps special knowledge in one branch, but they do not acquire a general grasp of the everyday practice. In the application of electricity for chemical operations we trust our experts will hold their own, and that the excellent laboratories erected at Birmingham for extending knowledge in this subject may be the first of a series of such equipments to be erected in all our manufacturing towns.

THE BRUSSELS INTERNATIONAL EXHIBITION OF 1897.

SIR,—But little attention has been given in this country to the international exhibition that is to be held in Brussels next year, probably for the reason that, until lately, it was wholly a private enterprise. The recent interest taken in the project by the Belgian Government has, however, invested it with considerable importance, and has converted it into an exhibition well worthy of the serious attention of manufacturers and industrials generally. The more important of our foreign competitors have signified their intention of participating in the exhibition: France has already made a grant of £35,000; Germany has appointed a powerful Government commission; in the United States a grant has been made by Congress; and a large number of other countries have accepted the invitation to be present, sent them by the Belgian Government. Our own Government has recently entrusted to an influential British commission, under the presidency of Sir Albert Kaye Rollit, the interests of this country at Brussels; and it now remains for our manufacturers to decide whether they will best consult their own interests by combining to form a representative British court, or whether they can afford to leave the opportunity for extension of business in the hands of our chief rivals—Belgium, Germany, the United States, and France. In urging them most seriously to consider, if not the direct advantages of participation, at least the great danger of abstention, I appreciate fully the cost and inconvenience inseparable from taking part in an exhibition; and if the one to be opened in Brussels next April had remained the offspring of a private company, I do not think it would have been worth the attention of manufactures. But having been adopted by the State, the International Brussels Exhibition of 1897 takes rank among the more important of its kind, and I do not think that this country can afford to be absent or not to be worthily represented there. This a question for exhibitors to determine, and to determine soon, as the time at their disposal is even now restricted. I shall be obliged to intending exhibitors if they will, at their earliest convenience, place themselves in communication with me, in order that I may furnish them with detailed information. I may add that the Brussels Exhibition is universal in its classification, embracing all branches of art, industry, and science.—Yours, etc.,

JAMES DREDGE,
(Executive Commissioner, British Section).

REVIEWS.

The Gas and Oil Engine. By DUGALD CLERK. Longmans, Green, and Co.

It is 10 years since the first edition of this book was placed before the public under the name "The Gas-Engine." Since then there have been several changes in it as new editions have been required. The most important additions have, however, been reserved till the sixth edition, now before us. The author claims in his preface that additions due to progress have been made rather than alterations in the original, and it is to his credit that such is the case. The parts dealing with oil-engines and with modern gas-engines form the bulk of the new work. In dealing with the various engines on the market or exploited, the author displays the critical knowledge of his subject much wanted in the present day, when so many books of the catalogue type are issued. This differentiating between the advantages of type is of great value both to the student and to the practical man. The large number of reliable tests of both gas and oil engines collected together in this book are interesting reading. Thus, the growth of the efficiency of gas-engines generally is shown by a series of tests on Crossley's engines dating from 1882. At that date a reliable trial showed that an engine took 23·7 cubic feet of gas per indicated horse-power. The London gas used at the trial was of such heating power that the indicated efficiency of the engine was 17 per cent. A Crossley engine of the same size tried by the Society of Arts in 1888 consumed 20·55 cubic feet of gas per indicated horse-power. The indicated efficiency with the particular gas used came out at 21 per cent., a considerable gain over the previous figures. Another trial made by the author in the autumn of 1894 on a 12-b.h.p. engine gave a consumption of 14·5 cubic feet of Openshaw gas per indicated horse-power. The efficiency was then found to be 25 per cent. The author compares the alterations in the engine cycle between these dates, and attributes the rise in efficiency to the increased compression of the charges. This was 38lb. per square inch above the atmospheric pressure in 1882, and rose to 87·5lb. in 1894. He proceeds to discuss the influence of the dimensions of the engine on the efficiency, and the possible increase in efficiencies for all causes. He arrives at the conclusion that in the last test referred to 80 per cent. of the heat available for external work had been used. The author commences the part of the volume devoted to oil-engines by a

Digitized by Google

description of the properties of the various types of oil on the market and available for the purpose. This part, which is most interesting to the general reader, is followed by detailed descriptions of 13 different oil-engines. These are fully illustrated, and in many cases tests of the engines are given. The general conclusions on the subject are contained in the last chapter, headed "The Difficulties of Oil-Engines." This contains much expert advice, which will be useful to the electrical engineer when choosing an oil-engine for installation work. The author has a strong objection to electric ignition arrangements, and thinks that the apparatus is likely to get out of order. This method of ignition did good service in the early days of oil-engines, but now can be replaced by recently-improved arrangements for getting incandescent tubes when using heavy oils. The further considerations of vaporising the charge and of engine governing are all treated in a critical but fair way. As a practical treatise for practical men we think this book has no equal.

The Story of Electricity. By JOHN MUNRO. Illustrated. George Newnes, Limited, London. Price 1s.

It would be difficult to find an author better qualified to write a book of a popular character upon electrical matters than Mr. Munro. Not only has he made himself familiar with the history of the subject, but he has also had a large experience in practical work, and, in addition, has a reputation as an author. Thus he knows his subject, knows his audience, and knows how to put his subject to his audience. The result is a very readable, instructive, and interesting little book—of course, almost purely descriptive, but none the less just the kind of book to give the general reader more correct views of the subject than many a pretentious tome.

ELECTRIC LIGHTING IN BELFAST.

We gave in full in our issue of July 31 the paper read by Mr. Victor A. H. McCowen before the Institution of Mechanical Engineers at Belfast. We are now able to give some of the illustrations accompanying this valuable paper. In Figs. 1 and 2 are shown curves of gas consumption, plotted from the results of tests on a tandem and on a single gas-engine; they show the total consumption per hour, per indicated horse-power per hour, and per electrical horse-power hour, and also the percentage of efficiency, or ratio of electrical horse-power to indicated horse-power. The engine of which the test, graphically recorded in Fig. 1, was made is a double-cylinder double-acting one, with the cylinders working tandem and the two pistons on the same rod. This is connected through a cross-head and connecting-rod to the crank. The bore of the back cylinder is 13¾in., and of the front 13½in.; the stroke is 20in. The

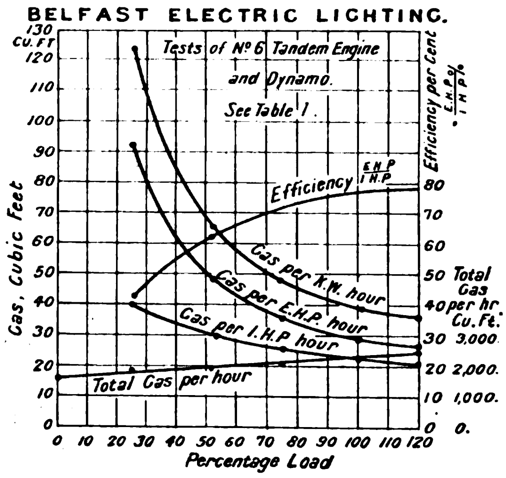

FIG. 1.

flywheel and driving wheel, one fixed on each end of the crankshaft, are each 8ft. 5in. diameter, and weigh 37cwt. and 29cwt. respectively; the driving wheel is grooved for eight ⅞in. ropes. This engine runs at a speed of 160 revolutions per minute and indicates 120 h.p.; the number of explosions per minute is 320, or two per revolution. The smaller engine, to which Fig. 2 applies, is a single-cylinder double-acting

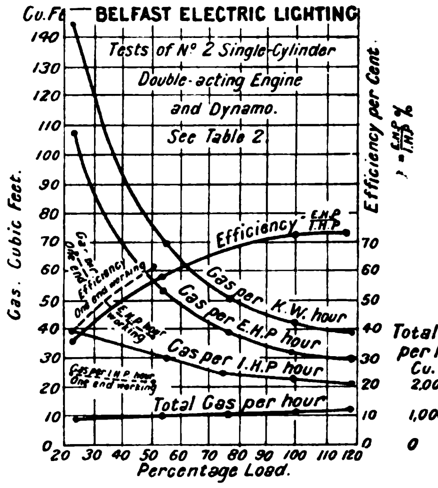

FIG. 2.

one; the cylinder is 13½in. diameter and 20in. stroke. It runs at 160 revolutions per minute, and indicates 60 h.p. The number of explosions per minute is 160, or one per revolution. The flywheel and driving wheel are each 7ft.

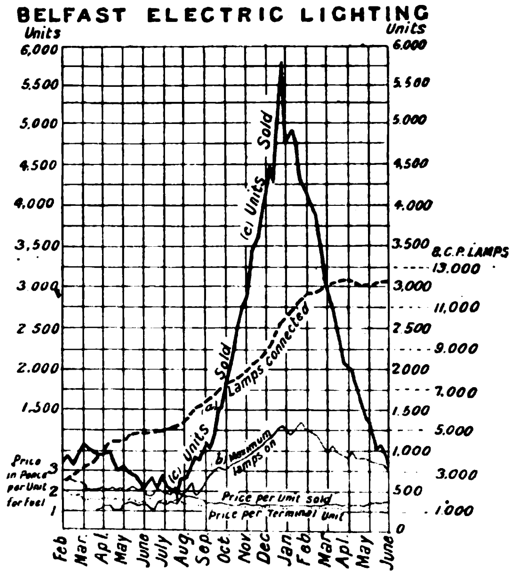

FIG. 3.

diameter, and each weighs 57cwt. The cyclical variation in the speed of the tandem engines is very small, owing to the number of explosions, their low initial pressure, and their even distribution, the number of explosions being as

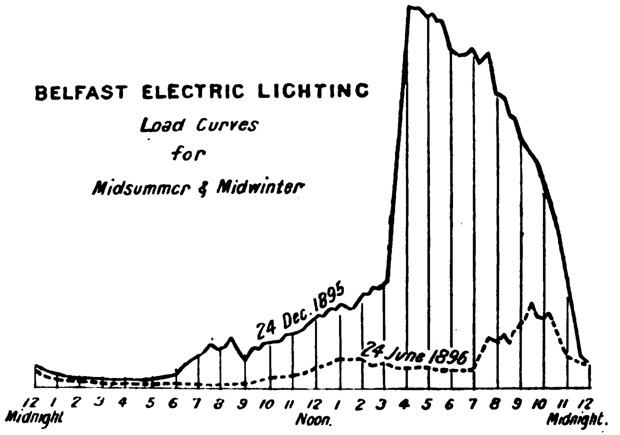

FIG. 4.

four to one in comparison with a single-cylinder single-acting engine. The results shown in these curves were tabulated in the paper, but the graphical record is much easier for reference. These engines, of which four of the

Digitized by Google

large size and two small ones are now installed at Belfast, were manufactured by Messrs. Dick, Kerr, and Co., of Kilmarnock.

The other curves deal with the loads on the station at different times. Thus Fig. 3 shows curves for (*a*) number of 8-c.p. lamps connected with the main, (*b*) maximum number of 8-c.p. lamps alight at one time, and (*c*) Board of Trade units sold per week since the station commenced the supply. By comparing curves *a* and *b* it will be seen that the number of lamps alight at one time has never been above 53 per cent. of the lamps connected. Curve *c* shows the great difference between the summer and winter output. The differences between the daily load curves in December and June are well shown in Fig. 4. As shops and offices together form a large percentage of the total consumption, the shape of the load curves depend greatly on their hours of closing. The Saturday curve (Fig. 5)

BELFAST ELECTRIC LIGHTING.

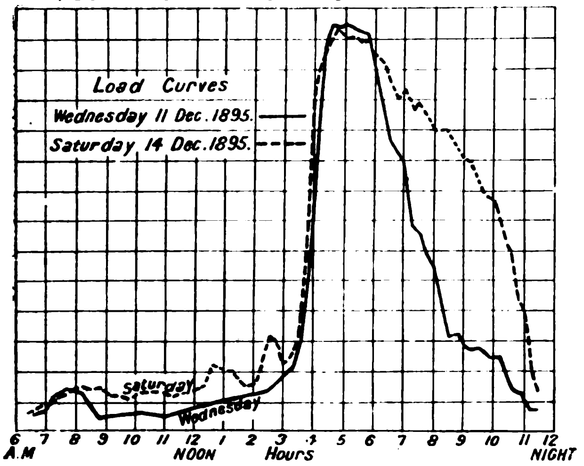

FIG. 5.

shows the effect of the late closing of some shops, a much better load being then given than on Wednesday, and with no very objectionable peak.

NOTES ON THE INTRODUCTION AND DEVELOPMENT OF ROPE DRIVING.*

BY ABRAM COMBE, FALLS FOUNDRY, BELFAST.

Introduction of Rope Driving.—So much has been said and written on the advantages and application of rope driving, and so many data and formulæ have been published from time to time, that it is hardly necessary to add to the information already available in these respects; but as rope driving emanated from Belfast, and has now grown to such large proportions in the industrial transmission of mechanical power, a short history of its origin, introduction, and development may prove of interest on the present occasion. Its introduction is due to the late Mr. James Combe, who in 1856 applied an expanding pulley with V-shaped sides to the differential motion of flax and tow roving frames. The expanding pulley was driven by a round leather rope from a driving pulley grooved with a V-shaped groove. In the course of his experiments in perfecting this motion, he was struck by the large amount of power obtained from round ropes working in V-shaped grooves, and this led him to try their application to the transmission of larger powers. With a view of arriving at the most effective angle for the grooves, a series of experiments were made in the Falls Foundry Works in the following manner: A pulley, fixed from revolving, was made with a number of grooves, each having its sides sloping at a slightly different angle from the others; ropes were then laid over these grooves with weights hanging from them at one end and counterbalance weights at the other; and the effect produced on the biting power of the rope in the groove by increasing and diminishing the weights and the counterbalance weights was carefully noted. The object was to determine in a practical manner the most suitable angle of groove for a driving rope, so that the rope should neither slip nor yet bite too much into the groove; and the angle chosen after the above simple experiments—namely, 45deg.—was adopted in the first pulleys set to work, and is at present generally used for rope driving under ordinary conditions. After several years' use of grooved pulleys and ropes for driving from the main shaft of one of the workshops at the Falls Foundry to that of another, the advantages of rope driving under certain conditions were found to be so great that, on the occasion of replacing one of the main engines in the beginning of 1863, rope driving was adopted for transmitting the entire power of the engine, amounting to over 200 h.p., from the second motion shaft to the principal shaft. This is the first instance of rope driving being used for a main drive of such importance, and the original pulleys are still in existence and working daily.

* Paper read before the Institution of Mechanical Engineers.

Material of Ropes.—About that date round ropes made of leather strips were generally used. These, however, were found to have the objection that they were liable to untwist, and the ends of the leather strips were apt to fly out during the working and cause trouble. Moreover, the strips of leather being cut out of the hide in a spiral were less strong where cut from the smaller diameters, and were liable to break at those parts. Manila ropes were then tried with good results, and leather ropes gradually gave place to ropes made from manila.

Relative Diameters of Ropes and Pulleys.—It was early recognised by the late Mr. James Combe that it is necessary to proportion properly the diameter of the ropes to the diameter of the pulleys on which they work; and he adopted the following minimum diameters of pulleys for the various sizes of ropes:

1¼in. diameter rope,	3ft. diameter pulley;	ratio,	1 to 28·8
1½in. „ „	4ft. „ „	„	1 to 32·0
1¾in. „ „	5ft. „ „	„	1 to 34·3
2in. „ „	6ft. „ „	„	1 to 36·0

Experience has shown that the results have not been so satisfactory when ropes of above sizes have been used on pulleys smaller than the above minimum diameters.

Power Transmitted.—When working under ordinary conditions the following simple bases were taken from which to calculate the power that each of the foregoing sizes of rope would transmit for each 100 revolutions per minute made by the pulley upon which it is working:

Rope 1¼in. diameter	on a 3ft. pulley	5	i.h.p.
„ 1½in. „	„ 4ft. „	8	„
„ 1¾in. „	„ 5ft. „	11	„
„ 2in. „	„ 6ft. „	15	„

and for other sizes of pulleys the power transmitted is calculated to be increased in direct proportion to the diameters of the pulleys. When working under the most advantageous conditions—for instance, where the ropes are running horizontally at good speeds, with the pulleys at a proper distance apart, and with the bottom rope acting as the driver—the above bases may be increased by 20 to 25 per cent. with safety. On the other hand, when the ropes are working under unfavourable conditions, with centres of pulleys too close together or ropes running vertically, these bases must be diminished by 20 to 25 per cent. The exact amount of increase or decrease on these standard bases has to be determined in each individual instance, according to the circumstances under which the ropes are working.

Speed of Ropes.—The speed originally adopted as being the most advantageous was about 3,300ft. per minute. This speed has since been far exceeded in many instances; but it is a question whether advantages have been reaped proportionate to the power gained by the increased speeds. On the contrary, the gain of power by increased speed is largely counteracted by loss of power from atmospheric friction and from centrifugal action; and when this loss is taken into account, along with the increased wear and tear on the ropes and bearings, the speed originally adopted, and speeds within certain limits of it, have been found to give the best results.

Extended Form of Rope Driving.—The new method of driving soon became known to several English and Scotch engineers, who joined in its further introduction and development. An extended form of main rope driving from the second motion shaft to the various lines of shafts in a flax mill is shown in Fig. 1. This drive was started in July, 1864, in the Hilden Mills of Messrs. William

Digitized by Google

Barbour and Sons, Lisburn, and is transmitting 600 i.h.p. Another of the earliest examples of rope driving from the flywheel of the engine itself was erected in 1873 at Owen O'Cork Mills, Belfast. This was designed by Messrs. Combe and Barbour, by whom also the pulleys were made, the flywheel being supplied to their instructions by Messrs. Hick, Hargreaves, and Co.

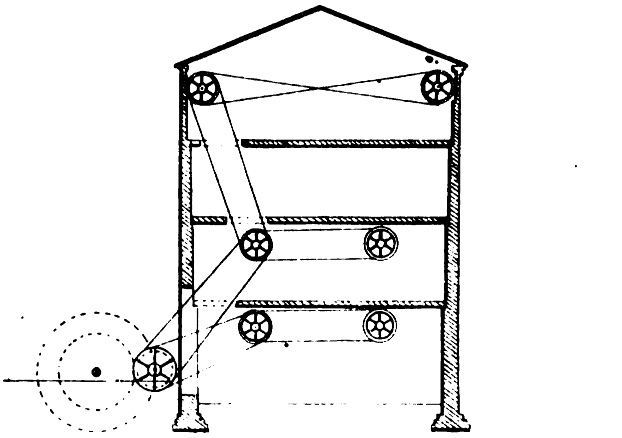

FIG. 1.—Main Rope Drive, 600 i.h.p., Hilden Flax Mills, Lisburn, erected 1864, and still running.

Cotton Ropes.—Later on in certain districts, especially those in which the cotton industry prevailed, cotton ropes began to be used. These have the advantage of being rather more pliable than manila ropes, especially when the latter are new. The relative merits of ropes made of manila and those made of cotton have frequently been discussed; but experience has shown that, if the pulleys are properly designed and applied, and if the ropes are the proper diameter, good results are obtained, whether the ropes are made of manila or of cotton.

Shafts Not Parallel.—One of the great benefits that was found in rope driving at a comparatively early stage was that ropes could be applied with advantage to transmit power between shafts that were not parallel. In 1875 a drive was put up in the works of Messrs. Combe and Barbour to deliver 100 i.h.p. from one shaft to another which was not quite parallel with it. Here the angle between the shafts was about 3deg., and the ropes were applied without making any alteration in the form of the grooves. When, however, it is desired to employ ropes for driving shafts at a greater angle, the grooves in the pulleys are altered to the section shown in Fig. 2, which was introduced about 1875, so as to allow the ropes to enter and leave the grooves without greater friction on their sides than when the shafts are parallel.

Endless Rope for Close Shafts.—In 1878 grooved pulleys and rope driving were introduced to replace pairs of large

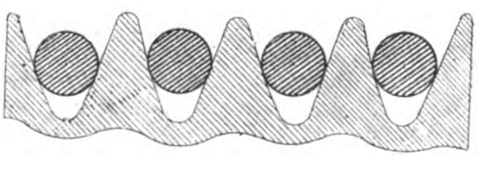

FIG. 2.—Section of Grooves when Shafts are at an Angle above 3deg., date 1875.

geared wheels, which from one cause or another were giving trouble; for example, in places where they were used to combine the power from a steam-engine with that from a waterwheel, or to combine the power from two engines working under slightly different circumstances. Here the centres of the wheels were so close together that ropes, if applied separately in the ordinary way, would have been too short for effective driving, and there would have been difficulty in putting equal tension upon each of the several ropes. Consequently, in order to secure a proper length of rope and equal tension, a single continuous rope was used which was laced round and round the pair of pulleys, passing from the first groove of the driving pulley to the first of the driven, thence back to the second groove of the driving pulley and on again to the second of the driven, and so on; and a tension pulley was added for leading the rope back from the last groove into the first.

Rope Flywheels.—The continued rapid extension of rope driving, and more especially of driving direct from the flywheel of the engine to the various shafts, led to designing flywheels to suit the high speeds. Mr. James Barbour, in 1879, designed a rope flywheel to meet the special requirements. The peculiar advantage of his method of constructing flywheels is that instead of depending solely on a cast-iron arm for connecting each segment to the nave, a strong wrought-iron bolt is used which passes down through the middle of the tubular cast-iron arm, and connects each segment directly with the nave; consequently, this bolt not only receives the tensile strain caused by centrifugal force while the wheel is in motion, but it also withstands the driving home of the cotters when the wheel is being put together. When cast iron alone is used for the arms, the driving home of cotters is a frequent source of breakage, which may not be detected until the flywheel gives way, whereas by driving the cotters into a long malleable-iron bolt there is less danger of fracture.

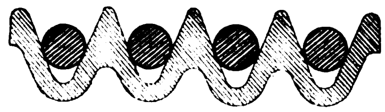

FIG. 3.—Section of Grooves for Curved Rope Drive, 1879.

Crossed Ropes.—It was about the same date that driving by crossed and half-crossed ropes was introduced; also that rope driving was applied to shafts working at right angles to each other, round corners, etc.

A special form of groove has to be used for cross-rope driving, so that each rope, though of necessity rubbing on itself, does not rub against its neighbours. The grooves are shown in the section, Fig. 3. They are constructed so that their pitch is greater than twice the diameter of the rope, as a further means of preventing the ropes from rubbing against their neighbours.

Endless Rope with Loose Guide-Pulleys.—In 1889 the arrangement of rope driving shown in Fig. 4 was introduced by Mr. James Barbour. Here the driving and the driven shafts were near together, and there was not sufficient space to apply the tension pulley previously described. A single continuous rope was therefore laced round the grooves of the pulleys, and for the purpose of leading the rope back from the last groove of the one pulley into the

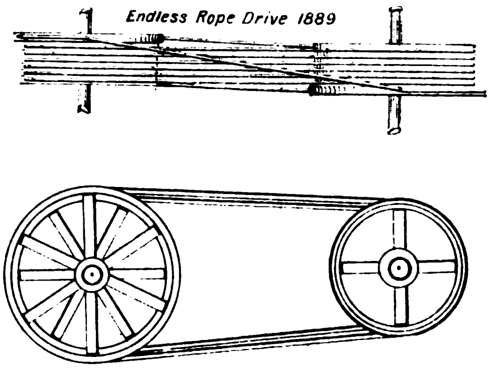

FIG. 4.

first groove of the other an additional single-grooved pulley was mounted loose on each shaft; these two loose pulleys were made larger in diameter than the fixed pulleys, and the rope was led from one to the other over the top of the ropes working in the grooves of the fixed pulleys. A large number of drives have been erected in this way, and all are working satisfactorily.

Endless Rope Driving Several Pulleys.—About the same date also a drive was erected, in which a single continuous rope was used for driving from one common pulley several shafts running at different speeds. In Fig. 5 is shown an example of one of these drives, in which a tension pulley is used to bring the rope back from the last groove into the first, and at the same time to take up the slack of the rope. In 1890 Mr. Barbour further developed the use of the single continuous rope, by applying it to the half-cross drive, in which by the peculiar method of lacing a single

Digitized by Google

endless rope is passed round the several grooves in succession, and back from the last groove to the first, without the intervention of a guide or tension pulley.

Substitution of Rope Driving for Geared Wheels and Relative Amount of Power Absorbed.—In many instances existing gearing and upright shafts have been thrown out and replaced by rope driving; and where the rope driving has been properly designed and erected, the total power required for the rope driving has in none of the installations which have come under the writer's observation exceeded that which was required when driving by wheel gearing; and in many cases the power required to drive the same amount of work by ropes has been less than it was before the change in method of driving took place.

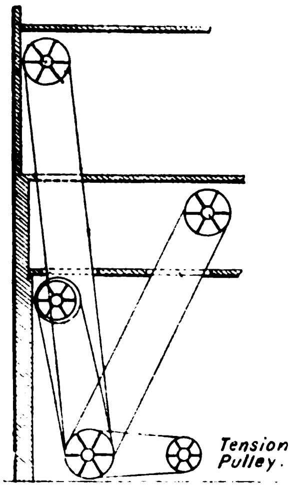

FIG. 5.—Single Endless Rope driving several Pulleys from One Common Pulley, 1889.

The above examples of the transmission of mechanical power by ropes serve to illustrate the development of this method of driving. Numerous variations have, of course, been made upon each of these plans, which have largely extended the field for the application of rope driving; so that this method of driving, which arose from such a small origin, is now widely adopted for industrial purposes. There is also no doubt that other developments will take place in the future, which will further extend its sphere of usefulness.

ON THE PROPER USE OF SAFETY FUSES AND MAGNETIC CIRCUIT BREAKERS.

BY WM. BAXTER, JUN.

In the days when electricity was truly in its infancy, one of the first facts discovered by those who were engaged in the actual operation of dynamos was, that some means must be provided for opening the circuit whenever the current strength rose beyond a certain limit. Two methods suggested themselves for accomplishing this result—the blow-out fuse and the magnetic cut-out.

The fuse became the most popular, owing principally to its cheapness and extreme simplicity. Notwithstanding all the good things that may be said of the fuse for past services, it is a crude device, and should only be used in what may be termed its own sphere of usefulness. This sphere is for the protection of branch circuits.

In a lighting plant all the branches may be protected by fuses, but in the main circuit they are of little, if any value, owing to the fact that their carrying capacity must be considerably above the normal current to avoid blowing out with such frequency as to be annoying. In branch circuits, if a fuse is used that will give way with a current of double the normal capacity, it will afford all the protection necessary, providing the wiring is of such proportions as to keep the line loss within reasonable limits. But if a fuse of similar proportions were used to protect a generator, it would be of no value. If the load on a generator is very uniform, a fuse may be used that is nearer to the normal current than two to one; but even under the most favourable conditions, if the margin is made less than 50 per cent., the frequency with which the fuse will blow out will be greater than would be admissible in most cases. Considering the foregoing facts, it is evident that a fuse placed in the main circuit of a generator will afford very little protection.

A question that has been agitating the minds of quite a number of central-station managers of late, and one which is worthy of very careful consideration, is whether it is advisable to use station safety cut-outs of any kind? Those who advocate discarding them claim that the occasional discontinuance of the current, when these devices act, causes dissatisfaction among the customers, and that it is better to suffer the loss caused by a burnt out armature now and then to loss of prestige in consequence of unsatisfactory service. There is a great deal of truth in this, and no doubt the desire to guard against loss occasioned by burn-outs due to excessive current is a relic of the days when economy of operation was considered of more importance than efficient service.

The use of safety devices may be entirely discarded in central stations without incurring the danger of burn-outs, if the capacity of engines and generators is in proper proportion. In cases where a number of machines are operated by a single engine, each one supplying an independent circuit, safety devices may be used, and the conditions may be made such that the cut-outs will very seldom come into action. To illustrate the truth of these statements, take the case of an engine driving a number of generators in parallel. All the safeguard necessary may be obtained by making the power of the engine less than the combined capacity of the generators, and providing each of the latter with an effective device for maintaining a constant E.M.F.

The common practice has generally been to have the engines of ample capacity to do the work; this, when properly interpreted, means that they should be of sufficient power to drive the generators at their maximum output, and still have a margin left for an emergency. But it is these emergencies that are fatal to the generator, and to provide the engine with a reserve capacity to meet them amounts to providing means for burning out armatures whenever the circuit becomes overloaded. If the steam-engine is overloaded, it will suffer no injury; the most that can happen will be that the speed will reduce, and if the overload is sufficient, the engine may be brought to a standstill. The generator is quite different, however, and, like the faithful horse, will work until it drops dead.

It may be said that even if the combined capacity of the generators is greater than that of the engine, there will still be danger of a burn-out, because the current in any one machine may rise above the average. This would be true, providing no provision were made to prevent such contingencies. Generally, generators coupled in parallel are connected by an equalising wire, which, while not able to maintain a perfect uniformity, tends to keep the difference in current so low as to be within the safe limit. Still greater certainty could be obtained by providing each generator with an automatic switch that would vary the resistance in the shunt circuit in accordance with variations in the strength of current passing through the armature.

If the generators are not connected in parallel, but are used to supply independent circuits, there will be little or no danger of burn-outs if the capacity of the machines is greater than the demands of the circuits they supply, and this danger can be made still less by using cut-outs set to act at a point just below the safe limit.

Where each generator is driven by an independent engine all danger of burn-outs from excessive current can be removed by this simple expedient of increasing the capacity of the generator. If you consult an engine-builder he will say that to drive a 100-kilowatt generator an engine of at least 175 h.p. should be used, and that 200 h.p. would be better. This advice he gives, because from his experience he believes that the generator would be forced beyond 100 kilowatts so far as to prevent good regulation with a smaller engine. Now if you instal a 100-kilowatt generator with a 200-h.p. engine, and then begin to overload the current, the generator will surely get into trouble before the engine begins to feel the strain. If you consult the generator manufacturer as to the size of engine, he will probably say that 150 h.p. is ample, but

Digitized by Google

even this is too much, if perfect safety is desired. To guard effectually against burn-outs, the proper plan to pursue is to ascertain the demand of the circuit, either actual or estimated, then provide engine capacity sufficient to meet this, making a fair allowance for loss in the generator, and a margin for abnormal demands. Then provide a generator that when working within the limit guaranteed by the makers will absorb the maximum power of the engine.

From the foregoing it will be seen that cut-outs and blow-out fuses in the main circuits of central stations and isolated plants are not necessary, and that all the protection they can possibly afford can be obtained by simply enlarging the capacity of the generators.

The only proper place for blow-out fuses is in branch circuits, and then they are necessary to prevent overheating the wires in case the current should become abnormally large from any cause.

Fuses are very generally used to protect motors, but for that purpose they are of very little value. A magnetic cut-out is the only proper safeguard for a motor, and to be of real value it should operate either with an excessive current or no current at all. It is not an uncommon thing for the current through a motor to be interrupted, and in such cases, if the switch is not opened, serious damage may be done when the current is established again. If the cut-out works both ways, mishaps in most cases will be avoided because as soon as the current stops the circuit will be opened.

There are cut-out switches of this kind on the market, and judging from their general appearance, they should be effective, but few of them are in actual use. The fuse is the mainstay and also the source of no small amount of annoyance, owing to the fact that it can be easily blown in the act of starting the motor if the attendant is inexperienced. Whenever they blow out there is more or less delay in inserting a new one, and also an expense which, although small, runs up to an appreciable amount by the end of the year. Owing to this annoyance and expense, the size of the fuse is increased in many cases to a point where it is simply no protection whatever, as it can carry more current than the motor. If cut-outs were used, they would be set to act nearer to the working capacity than is the case with fuses, because if they should act, they could be reset in a few seconds by the simple movement of the lever.—*Electrical Engineer* (New York).

ALTERNATE-CURRENT MOTORS.

We referred in our issue of the 7th inst. to some motor tests by Prof. D. C. Jackson, which were the subject of a paper read before the North-Western Electrical Association of America. We are now able to give the curves and table of efficiencies, etc., as promised then. The chief fault with the arrangements is that the type of the different motors tested is not given with the test figures. Thus, the eight m tors included the following types and makes, and we can only assume that they are given in the order listed: A Fort Wayne Electric Corporation single-phase motor, a Stanley Electric Manufacturing Company two-phase motor, a Westinghouse Electric and Manufacturing Company two-phase motor, a General Electric Company three-phase motor. A 5-h.p. three-phase motor made by the Allgemeine Electricitäts Gesellschaft of Germany was also tested, and the results of tests on motors made at Oerlikon and at Brown and Boveri's works are included in the tables. A 10-h.p. Westinghouse two-phase motor was tested, but not up to its maximum load. Five-h.p. motors were selected to be tested, as that may be considered to be near the average capacity of motors used in the service of ordinary central stations. Prof. Jackson thinks that the results of the tests may, therefore, be accepted as representing, for the central stations, comparative results between the average motors which they may use on alternating-current systems. The results may also serve as a basis for comparison between average conditions of operating with continuous-current and alternating-current motors. Four out of the six motors tested are said to have affected the incandescent service disastrously, and showed the absurdity of attempting with them a combined service on

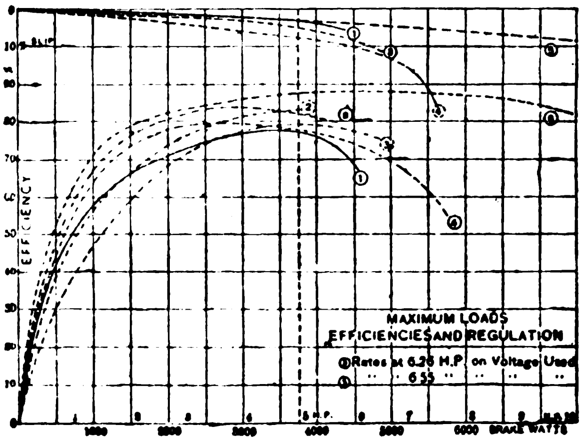

Diagram of Efficiencies and Power Factors.

the same circuits as the incandescent lighting in those plants where regulation and the satisfaction of the customers is considered of importance. The tests show, according to Prof. Jackson, that the alternating current motors give equally satisfactory regulation and efficiency as is given by continuous-current motors, but the power factors of most of the machines are small for part load, the starting currents excessive, and the starting torques with the present arrangement of starting resistances are unduly small. The best performance of the American 5-h.p. machines lies between No. 3 and No. 5 of the tables. These machines stand well above the others. They are about even in starting torque, but No. 5 will carry considerably higher torque before dropping out of step completely; No. 5 also regulates the better and has the higher efficiency. On the other hand, No. 3 has a power factor incomparably better than any of the other machines.

As mentioned above our chief objection to the arrangement of the table is that due to the confusion of types. Single-phase motors are never so efficient as two or three-phase motors of the same output, and hence it is misleading to compare them directly. Again, when the alternating system has been established on the single-phase system the type of motor is fixed, and hence the figures for multiphase work do not apply. We also regret that the frequency at which the different tests were made is not listed.

SCIENTIFIC EDUCATION IN GERMANY AND ENGLAND.

BY PROF. W. OSTWALD

In our frequent discussions on scientific education, we have both often been struck with some points of very great difference between the English and the German way of dealing with it. As it may be asserted without national arrogance that university education is in Germany in a more satisfactory condition than in your country, you are, of course, anxious to know which of the German customs I consider most effective in bringing about this better state of things, and I will, therefore, try to point them out. Of course, I shall confine myself to the subject of natural science, and especially chemistry and physics, feeling myself unable to deal with sciences beyond my knowledge. The main point of our system may be expressed in one word—freedom—freedom of teaching and freedom of learning. The first involves for the teacher the necessity of forming in his mind a clear conception of the scope of his science, for, as he is free to choose any possible method of view, he feels himself answerable for the particular one he has chosen. And in the same way the student feels himself responsible for the method and the subjects of his studies, inasmuch as he is free to choose any teacher and any subject. One who has not seen this system in action may be inclined to think that such a system must lead to arbitrary and irresponsible methods on the side of the teacher, and to confusion on the part of the student. But the former is avoided, because at the beginning of his career the teacher is dependent for his advancement on the results of his scientific views, and is naturally anxious to improve his position in the educational world. And as for the students, they themselves impose certain restrictions on their own freedom. Most of them feel that they require some advice and guidance, and they therefore follow the usual and approved order in conducting their studies. As to the inventive man of original ideas, it has often been proved that for him any way is almost as good as any other, for he is sure to do his best anywhere. Moreover, such a man very soon excites the interest of one of his teachers and is personally led by him, generally to the great advantage of both.

Let us illustrate these general remarks by considering the course followed by an average chemist. In his first half-year he hears lectures on inorganic chemistry, physics, mineralogy, sometimes botany, and of late often differential calculus. Moreover, the German student is accustomed to take a more or less strong interest in general philosophy or history, and to add in his *Belegbuch* (list of lectures) to the above-named *Fachcollegien* (specialised studies) one or two lectures on philosophy, general or German history, or the like. Very often there are in the university one or more popular professors whose lectures are heard by students of all faculties without reference to their special studies. The student who has heard during his stay at the university only lectures belonging strictly to his *Fach* is not well thought of, and is to some extent looked down on as a narrow specialist. But I must add that such views are not prevalent in all faculties, and there are some—*e.g.*, the faculty of law—whose students confine themselves, with few exceptions, to attending exclusively lectures in that faculty.

In the second half-year the chemical student begins with practical laboratory work. Notwithstanding the perfect freedom of the teachers, the system first introduced by Liebig into his laboratory at Giessen is still universally adopted in German universities and technical high schools—viz., qualitative and quantitative chemical analysis, the former conjoined with simple spectroscopic work, the latter amplified by volumetric analysis. This is followed by a course of chemical preparations, formerly chiefly inorganic, now chiefly organic. Even here, a regular system is being widely developed owing to the use of some well-known text-books. Of late years this course is followed in some laboratories by a series of exercises in physical chemistry and electro-chemistry.

While these practical exercises, which last for three or four half-years, are being carried out, the student completes his knowledge of physics, mathematics, and the other allied sciences by hearing lectures and working practically in the physical and often also in some other laboratory. The exercises done, he goes to the professor and asks him for a "theme" to begin his "work"—viz., his dissertation for the degree of Dr.Phil. This is the most important moment in his life as a student, for it generally determines the special line of his future career. The "theme" is usually taken from the particular branch of the subject at which the professor himself is working; but, as the scientific name and position of the professor depends, not only on his own work, but to a large extent on the work issuing from his laboratory, he is careful not to limit himself to too narrow a range of his science.

Of course, it is best of all if the student selects for himself a suitable "theme," suggested to him by his lectures or practical work, or from private study of the literature of the science. But this seldom happens, for the young student is not yet able to discern the bearing of special questions, and lacks knowledge how to work them out. Sometimes (but not very often indeed) he points out to his professor in a general way the kind of problems he would like to work at, and the professor suggests to him a special problem out of this range of subjects. During the working out of his chosen subject the student learns generally much more than he has heard at lectures. Every part of the investigation forces him to revise the scientific foundations of the operations he performs. During this time the incidental short lectures given by the professor on his daily round from one to another of the advanced students are most effective in deepening and strengthening the student's knowledge. As these explanatory remarks are generally heard not only by the student whose work has caused them, but also by a number of fellow students working near, a fairly wide range of scientific questions are dealt with in their hearing. Often these small lectures develop themselves into discussions, and, as for myself, I judge from the frequency of such discussions between the students whether the session will turn out a good one or not. If the professor thinks the work sufficiently complete to be used as a dissertation, the student proceeds to the close of his studies. He prepares himself for the examination, which is conducted by the very professors whose lectures he has heard, and in whose laboratories he has worked. This examination varies somewhat in different universities, but in no case is it either very long or extensive; indeed, it is not considered as very important, for we are all aware what an uncertain means of determining a man's knowledge and capabilities and examination is, and how much its issue depends upon accidental circumstances. Part of this uncertainty is removed by the fact that the professor and the pupil know each other, are acquainted with one another's modes of expression and scientific views. The main purpose of the examination is to induce the student to widen his knowledge to a greater extent than is covered by the subject of his dissertation; but, indeed, it happens very seldom that a student whose work is considered sufficient does not pass the examination.

We have no great fear that this system may induce a professor to treat his own pupils in too lenient a way, and so lower the standard of the doctor's degree. There was a time when such abuses used to occur, but there very soon arose such public indignation that the abuses ceased to occur. Even at the present day similar instances occasionally occur, but, as before remarked, the position of a professor depends in such a degree upon the value of the dissertations worked out under his supervision that such deviations from the right way correct themselves in the course of time. The most effective instrument for that purpose is the publication of all dissertations and the consequent public control over them; for this reason publication is, I believe, compulsorily prescribed in all German universities.

When the student has finished his course he is still entirely free to choose between a scientific and a technical career. This is a very important point in our educational system; it is made possible by the circumstance that the occupation of a technical chemist in works is very often almost as scientific in its character as in a university laboratory. This is connected with a remarkable feature in the development of technical chemistry in Germany—the very point upon which the important position of chemical manufacture in this country depends. The organisation of the power of invention in manufactures, and on a large scale, is, as far as I know, unique in the world's history, and it is the very marrow of our splendid development. Each large work has the greater part of its scientific staff—and there are often more than 100 *doctores phil.* in a single manufactory—occupied, not in the management of the manufacture, but in making inventions. The research laboratory in such a work is only different from one in a university by its being more splendidly and sumptuously fitted than the latter. I have heard from the business managers of such works that they have not unfrequently men who have worked for four years without practical success; but if they know them to possess ability they keep them notwithstanding, and in most cases with ultimate success sufficient to pay the expenses of the former resultless years.

It seems to me a point of the greatest importance that the conviction of the practical usefulness of a theoretical or purely scientific training is fully understood in Germany by the leaders of great manufactories. When, some years ago, I had occasion to preside at a meeting, consisting of about two-thirds practical men and one-third teachers, I was much surprised to observe the unhesitating belief of the former in the usefulness of entirely theoretical investigations. And I know a case where, quite recently, an "extraordinary" professor of a university has been offered a very large salary to induce him to enter a works only for the purpose of undertaking researches regarding the practical use of some scientific methods which he had been working at with considerable success. No special instructions are given to him, for it is taken for granted that he himself will find the most promising methods; only, in order to increase his interest in the business, part of his remuneration has been made proportional to the commercial success of his future

Digitized by Google

inventions. From this clear understanding of the commercial importance of science by the directors of industrial establishments there science itself gains another advantage. A scientific man can be almost sure, if he wants in his investigations the help of such technical means as only great works can afford, that he will get such assistance at once on application to any work; and the scientific papers of German chemists very often contain acknowledgments, with due thanks, of considerable help they have thus obtained.

Besides these advantages for the development of scientific and technical chemistry in Germany there exists another very important factor—practical assistance from the Government. Universities are in Germany affairs of the State, not of the Empire, and in no other point has the division of the Fatherland into many smaller countries proved itself to such a degree a boon and a blessing. The essential character of the German universities, the freedom conferred by the independence of the numerous universities, is never lost. There have been hard times occasionally for the universities of one country or another; but some universities were always to be found where even in times of hard oppression liberty of teaching and learning remained complete and unaffected, and the spirit of pure unalloyed scientific research was preserved and encouraged. So this palladium of intellectual freedom has never been lost; and it regained the former influence as soon as the casual oppression ceased. In our days there is among all the separate State governments in Germany a clear conviction of the importance of practical support being given to pure scientific research. To take one instance, in order to facilitate teaching and research in electro-chemistry—a recently developed branch of science—a suggestion by some leading practical scientific men to the members of the Government was sufficient. Upon such a suggestion a considerable sum of money was spent first by the Prussian Government for the endowment of electro-chemical chairs and laboratories in the three "polytechnic" colleges of that country; a short time afterwards it was resolved to erect at one of the universities, Gottingen, an institute for physical chemistry, and especially electro-chemistry, in the shape of a building which has just been completed. At the same time other German countries have begun to grant to their universities and technical colleges considerable sums of money for similar purposes—*e.g.*, the Saxon Landtag alone has unanimously voted half a million marks (= £25,000) for the erection of a splendid laboratory for physical chemistry at Leipzig.

You will excuse my boasting about our German management of this most important question of scientific education. It is no blind admiration without criticism, for I know by practical experience the management in other countries, and I can compare them. And it is only for the sake of science itself that I write these lines. If they should help the spread of the conviction of the incomparable practical usefulness of every support given to pure science, together with the recognition of the fact that the latter can only grow in an atmosphere of liberty and confidence, I should regard it as tending towards the progress of science itself and destined to exercise such an influence on scientific progress as may be compared with the discovery of the most remarkable scientific fact.

The foregoing is a letter written by Prof. Ostwald, the founder and editor of the *Journal of Physical Chemistry*, to Prof. W. Ramsay, of University College, and inserted by him in the *Times*.

LEGAL INTELLIGENCE.

A THREAT TO CUT TELEPHONE WIRES.

In the High Court of Justice, Chancery Division, on August 26, the case of the National Telephone Company, Limited, *v.* Armand was heard before Mr. Justice Chitty.

This was a motion by the plaintiff company for an interim injunction to restrain the defendant, until the trial of the action or further order, from using or communicating in breach of confidence, and to the detriment of the plaintiffs, any information obtained by him while in their service, and also from cutting, destroying, or damaging any telephone wires or posts of the company.

Mr. Baker, who, with Mr. Heckscher, appeared in support of the motion, stated that the defendant had been employed by the company as wayleave officer, his business being to obtain permissions for carrying their wires over private property, and had acted in that capacity for something over 12 months. The district superintendent, on July 23, gave the defendant notice terminating his engagement on the 30th, and thereupon he wrote to the general manager asking that the matter might be looked into Though the general manager had refused to interfere with the action of the district superintendent, the defendant was offered a berth as canvasser at a salary of 25s. a week, but this he refused to accept, and in his letter to the general manager intimated that if the decision was not reconsidered he should assume an attitude of bitter antagonism to the company. Since then he had threatened to cut down the wires unless a certain rent was paid for the wayleave he had obtained for overhead wires.

The **Defendant** appeared in person, and, in answer to his Lordship, before the case for the plaintiffs was opened, said he had no evidence to put upon affidavit.

Mr. Justice Chitty: I must grant an injunction. The plaintiffs will give an undertaking in damages, and there will be the usual order. I warned the defendant before the case was opened of the position in which he would find himself if he gave no evidence. The case is really undefended, and the inference to be drawn is that the information was obtained by the defendant in the manner suggested by the plaintiffs. The plaintiffs' costs will be costs in the action.

COMPANIES' MEETINGS.

BRUNNER, MOND, AND CO., LIMITED.

The half-yearly meeting of Brunner, Mond, and Co., Limited, was held in Liverpool on August 20, Sir John T. Brunner, M.P., presiding.

The **Chairman** moved the adoption of the report, showing a total profit for the half-year of £276,031, and proposing to pay a 7 per cent. dividend on the preference shares and 30 per cent. on the ordinary, and carrying forward £96,544, after placing £18,658 to reserve and £500 to patents accounts, and it was agreed to.

A subsequent extraordinary meeting was held to deal with a special resolution for increasing the capital from £2,000,000 to £3,000,000 by the creation of new stock, and to make contracts with any of the directors for occasional services, and to make yearly balance-sheets in future, etc.

The **Chairman**, in moving the resolution, said that increasing the capital from £2,000,000 to £3,000,000 seemed rather a big jump, but if the 7,906 preference shares were taken up, the £2 000,000 would be fully exhausted, and it was only paying a little sooner than otherwise the £1 per thousand of duty to the State. As to the proposal to issue yearly balance-sheets, it was found that taking stock twice a year was putting such a strain upon the staff that they thought it ought not to be done. An interim dividend would, however, be paid.

The proposals were unanimously adopted.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

The third annual general meeting was held at Winchester House yesterday (Thursday), Sir Daniel Cooper, Bart., in the chair.

The **Chairman**, in moving the adoption of the report and accounts, which were published in our issue of August 7, pointed out that the net profit for the year amounted to £16,450, and adding to this £10,135 carried over from last year, the amount available for dividend was £26,585, of which the directors recommended that £13,288 be paid in dividend of 5 per cent.

The report was adopted, and the retiring directors re-elected.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Paris.—Tenders are wanted by September 8 for the supply of magneto-electric calls for the Departments of Posts and Telegraphs, rue de Grenelle 103, Paris.

Dantzig.—Tenders are wanted for the supply of incandescent lamps and carbons. Particulars for 75 pf. (9d.) from the Konigliche Direction der Gewehrfabrik, Dantzig.

Dortmund (Germany).—The Municipal Authorities of Dortmund want tenders by September 1 for engines, boilers, and dynamos for the electric lighting of the town.

Spa (Belgium)—The Burgomaster and Echevins of Spa invite propositions for undertaking the public lighting, either electrically or by acetylene. The date fixed is September 15. No further information is given in the official advertisement.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

The Hague.—The Consul-General of the South African Republic demands tenders for the supply of copper wire for the Telegraph

Digitized by Google

Department of the South African Republic. Tenders which have not been received before September 1, Doelenstrat, No. 8, at Amsterdam, will not be regarded. Specifications will be procured on demand by F. J. Belinfante, late A. D. Schinkel, Paveljoensgracht, The Hague, Holland, at the price of 1sh. pro tender.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Oldham.—The Electric Light Committee invite tenders for the various works required in the extension and alterations of the buildings of the electric light station in Gas-street, Oldham. Specifications and drawings can be seen, and schedules of quantities obtained, on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham. A charge of £1. 1s. will be made for the schedule of quantities, which will be returned on receipt of a bona fide tender. Tenders to be sent in by September 15.

Hull.—Pending the decision of the Town Council as to the leasing of the tramways or the working of them by the Corporation, tenders are invited for a license to temporarily work and use the tramways for one year from October 15, 1896, upon the terms and conditions embodied in the draft of an agreement, which can be obtained by application to Mr. R. Hill Dawe, town clerk, Town Hall, Hull. Tenders, stating the amount of rent offered, must be delivered at the Town Clerk's Office, by 10 a.m. on September 21, in sealed envelopes, endorsed "Tender for Temporary Working of Tramways."

Bristol.—The Electrical Committee require tenders for additions to the electric lighting station, Temple Back. The plans may be seen, and copies of the specifications, forms of tender, and bills of quantities may be seen and obtained at the office of the architect, Mr. Henry Williams, 24, Clare-street, Bristol, on payment of £3. 3s., which will be returned on delivery of a bona fide tender. Tenders must be delivered by noon on September 4, addressed to the Secretary, Electrical Department, Temple Back, Bristol, and endorsed "Tenders for Additions to Central Station."

Southampton.—The Harbour Board invite tenders for the construction and erection of four electric cranes and accessories, and also for alterations to a gantry of an existing crane, on the Town Quay, Southampton. Specification, with two general drawings attached, may be obtained on and after 20th inst. from Mr. A. H. Skelton, clerk, Town Quay, Southampton, upon payment of £3. 3s., which will not be returned, and further detailed plans may be seen at the office of the electrical engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster, S.W. Sealed tenders, marked "Tenders for Electric Cranes," should be sent to the clerk by August 31.

Blackpool.—The Corporation are prepared to receive tenders for the supply, laying, and maintenance of high-tension and low-tension lead-covered cables and the supply of all necessary jointing sundries. Specifications and bills of quantities, together with forms of tender, may be obtained from the Borough Electrical Engineer, on payment of 10s. 6d., which will be returned on receipt of a bona fide tender. Tenders, addressed to the Chairman of the Electric Lighting and Tramways Committee, and endorsed "Tender for Cable," should reach the offices of Mr. Robt. C. Quin, borough electrical engineer, Corporation Electricity Works, Blackpool, not later than September 8.

Jassy.—The Mayoralty of the Town of Jassy (Roumania) has given notice that on August 23, 1896, old style (by our reckoning September 4), tenders will be received, for the second time, in the hall of the Municipal Council, for "the installation of a frigorific hall, electric light, and various accessories requisite for new public slaughter-houses. Offers must be in accordance with the specification, the conditions of contract, the special conditions, and the plans deposited in the offices of the director of the slaughter-house works, where particulars may be obtained." Tenders are to be enclosed in sealed envelopes, marked "Offre pour l'installation de la Hall Frigorifique," and senders of tenders must abide by articles 68-79 of the Roumanian Public Accounts Act. All tenders and supplementary documents must be in either the Roumanian or French language.

Cadiz.—The Secretary of State for Foreign Affairs has received dispatches from her Majesty's Consul at Cadiz, stating that preliminary tenders for a supply of electric lighting apparatus for the illumination, on the most approved modern plan, of private houses, etc., in the town of Cadiz are invited by the "Sociedad Co-operativa Gaditana de Fabricacion de Gas." It appears that the tenders should be sent in by September 15 to the above-named company, whose offices are San José, 25, 27, and 29, Cadiz. Firms wishing to obtain the contract for the supply of plant are advised by the Consul to send representatives to treat personally with the company. Such additional particulars as have reached her Majesty's Government on the subject may be viewed at the Commercial Department of the Foreign Office, any day between the hours of 11 a.m. and 6 p.m.

Bath.—The Corporation invite tenders for the supply and erection of the following plant:—Section A: Boiler and fittings, feed pump, etc. Section B: Steam alternators, oil-filter, fittings, etc., steam, exhaust, feed, blow-off, and sundry pipes, valves, etc. Section C: Mains. Section D: Crane. Section E: Arc lamps and posts. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plan of plant and specification, with terms and conditions of tender and contract, may be obtained at the office of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, E.C., on and after the 13th inst., on payment of £2. 2s., which will be returned on receipt of a bona fide tender. Sealed tenders, marked "Tender for Electric Lighting," must be addressed to Mr. F. H. Moger, clerk, 3, Wood-street, Bath, and delivered by the 31st inst.

Cork.—The Mayor, Aldermen, and Burgesses of the city or borough of Cork invite tenders from persons or companies willing to carry into effect the powers conferred upon the Corporation of Cork by the electric light provisional order of 1896. The Corporation of Cork have made arrangements with a tramway company, who propose installing an electric tramway system in Cork, whereby the supply of current for the tramways must be taken by the tramway company from the assignees of the electric light provisional order, and the advantages of this arrangement are specially pointed out to the intending tenderers. A copy of the conditions under which the order may be transferred, and form of tender, prepared by Messrs. Kincaid, Waller, and Manville, may be obtained from Mr. Alexander M'Carthy, town clerk, Municipal Buildings, Cork, on payment of £1. 1s., which sum will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Application for Transfer of Electric Light Provisional Order," to be sent by 12 noon on September 11 to the Town Clerk.

RESULTS OF TENDERS.

Coventry.—For installing the electric light at the Technical Institute the tender of the Coventry Gas Fittings Company, at £250, was accepted.

Coventry.—For carrying out extensions at the electric lighting works the contract of Messrs. MacCarthy and Co., Well-street, at £1,150, has been accepted.

BUSINESS NOTES.

Douglas.—The cable tramway, constructed by Dick, Kerr, and Co., was opened for public traffic on Saturday last.

South Shields.—We are informed that the Corporation electricity works will be opened on September 1, and the current will be turned on at 7.30 p.m.

Hull.—The Corporation recess has commenced, and will continue until September 24, when the Electric Lighting Committee will be the first to meet.

Dover.—The Dover Corporation have decided to light the sea-front throughout the season by festoons of 1,000 32-c.p. incandescent electric lamps, in addition to the ordinary arc lights.

Western and Brazilian Telegraph Company.—The receipts for the week ending August 21, after deducting 17 per cent., payable to the London Platino-Brazilian Telegraph Company, were £2,605.

Dewsbury.—Formal resolutions were passed at the meeting of the Guardians consenting to the expenditure already incurred of £630 for the electric light. The sum previously sanctioned amounts to £2,150.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending August 23 amounted to £1,363, as compared with £1,318 in the corresponding week of the previous year, being an increase of £45.

Institute of Chemistry of Great Britain and Ireland.—Mr. A. E. Parkes, who during the past three years has been a student at Mason College, has passed the intermediate examination of the Institute of Chemistry held in July.

Alteration of Address.—Messrs. Honeywood, Austin, and Co., makers of labour-saving tools and machinery, have taken the Grove Works, Harleyford-road, Vauxhall, which have been fitted up with an entirely new and modern plant.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending August 21 were £2,517. 14s. 1d., compared with £2,083. 0s. 4d. for the corresponding period of last year, being an increase of £434. 13s. 9d.

Brussels.—The *Daily Chronicle* states that the concession for constructing an electric railway along the downs between Ostend and Middlekerke has just been signed between the Belgian authorities and the late Colonel North's executors.

Stockport.—An electric plant is being put down at Gaghill's Slipper Works by Messrs. Richardson, of Romiley, near Stockport. The work is being pushed on at all speed, and the coming autumn will see the large works lighted throughout with electricity.

Wrexham.—At a special meeting of the Council it was resolved that an application should be made to the Board of Trade for a provisional order to authorise the Corporation to supply electricity for public and private purposes within the borough and certain adjacent districts.

Llanelly.—The Estate Committee of the Borough Council had under consideration at their meeting a proposal of Mr. J. C. Howell for the electric lighting of the town. No definite decision was come to, the discussion being adjourned so as to enable the surveyor to make further enquiries.

City and South London Railway.—The returns for the week ended August 23 were £969, compared with £875 for the corresponding period of last year, being an increase of £94. The total receipts for the half-year 1896 were £7,498, compared with £6,883 last year, being an increase of £615.

Digitized by Google

Bridgwater.—Alderman Peace, Councillor Waddon, and the borough surveyor have been appointed a sub-committee by the Town Council to visit other towns and make such enquiries as they might consider necessary and desirable in connection with lighting the town by means of electricity.

Folkestone.—At the meeting of the Corporation the reception and consideration of the preliminary report of Dr. Hopkinson on the provisional agreement with Mr. Hopkins, and the terms and conditions of the proposed transfer to be entered into between the Corporation and the electric lighting company was left over.

Arundel.—The electric lighting arrangements at Arundel Castle are being rearranged. It is said that the supply includes over 2,000 lamps, and the placing of them to the greatest advantage has been the subject of careful study. The plant is of a most complete character, the machinery being duplicated throughout.

Bexhill.—A long discussion took place at the meeting of the Urban District Council on the recommendation of the Highways Committee that the Council should reserve to themselves the right to purchase the proposed electric lighting undertaking by arbitration. Eventually the matter was referred back to the committee

Witton Gilbert. — Councillors Embleton, Holmes, and the chairman have been deputed by the Parish Council to see that the services of an electric lighting expert be secured, and the work inspected by him at once, the Corlett Electrical Company's account being left in abeyance until the expert's report was received.

Central London Omnibus Company, Limited.—This Company has been started, with a capital of £1,000, to carry on in the United Kingdom and elsewhere the business of electricians, electrical and mechanical engineers, manufacturers and owners of electrical vehicles and carriages, and dealers in electricity, electric machines, appliances, apparatus, motive power, traction, heat, and light.

Huddersfield.—At the meeting of the Corporation, the minutes of the Parks and Cemetery Committee showed that the question of illuminating the Greenhead bandstand by electricity—the cost of the main being estimated at £40 if laid underground and £18 if erected overhead—had been deferred *sine die*, but permission had been given to Messrs. Read Holliday to light it with acetylene, if the cost of the experiment was borne by the firm.

Nottingham.—The extensions of the buildings at the electric lighting station, Talbot-street, are now rapidly approaching completion. The size of the structure will be practically doubled, and there are to be three new boilers and two new dynamos, each of 360 h.p. The building operations have been carried out under the superintendence of the borough engineer, Mr. A. Brown, whilst the erection of the plant has been under the direction of the electrical engineer, Mr. H. Talbot.

Portsmouth.—A special committee of the Portsmouth Town Council have decided to recommend the municipal body to apply for a provisional order next session to authorise the purchase of the local tramlines owned by the Provincial Company. The estimated cost is £60,000, and the cost of taking up the lines and relaying them for electric cars would, it is believed, cost £90,000, making a total of £150,000. It is proposed to let the lines to the company at a rental which would allow of a profit.

The Great Wheel at Earl's Court.—The difficulties which have hitherto prevented the placing of an illuminated advertisement on the Great Wheel have been at last surmounted by Mr. Seymour Wade, in conjunction with Messrs. Foote and Milne, the electrical engineers, and it is announced that towards the end of this month the advertisement of a well-known London company will flash out of the darkness of the night in letters 30ft. high, 300ft. from the the ground, readable by the naked eye for 10 miles round.

City and Guilds of London Institute.—The programme of technological examinations, including regulations for the registration and inspection of classes in technology and manual training, has just been issued. The acting examiners for the year include the following: photography, Mr. Lyonel Clark and Mr. J. D. Geddes; telegraphy and telephony, Mr. J. Gavey; electric light and power distribution, Prof. W. E. Ayrton, F.R.S., and Mr Jas. Swinburne; electro-metallurgy, Prof. W. G. McMillan; and salt and alkali manufacture, Mr. A. E Fletcher.

Astley Bridge.—A special meeting of the District Council has been held to consider a resolution passed by the special committee of the Town Council on the electric traction of the tramways inviting representatives from the Astley Bridge Council to a conference of the authorities interested in the matter. In the course of the discussion it was stated by the clerk that the lease of the Astley Bridge tramways expires on September 1, 1901. The chairman of the Council (Colonel Hesketh), Captain Greg, and Mr. Orrell were deputed to attend the conference.

Electricity in Laundry Work.—The fourth annual Laundry and Sanitary Exhibition is being held at the Agricultural Hall, Islington, this week. A leading feature is the exhibit of motor-cars, for which a track 16ft. wide has been made round the galleries. A pond, 100ft. long by 6ft. wide, has also been made, on which to show electrical and other boats. The uses of electricity in laundry work are also shown, several electrical hydro-extractors being on view, as well as electrical arrangements for heating and driving ironing machinery of various descriptions.

Liverpool.—The extension of the overhead railway is being continued, and it is within the bounds of probability that cars driven by electricity may some day complete the circle around the city. The railway runs alonside of the docks from end to end, and some distance beyond. The electric power is being used just now for the purpose of painting the exterior of the structure, the paint being put on by means of a spray attached to a machine, which is worked from the electric conductor on the railway, thereby reducing the cost of skilled labour in this department from 20s. to 11s. 6d.

Clontarf. — The Dublin United Tramway Company are completing arrangements for the electrical equipment of their line to Clontarf. It is expected that the work will be commenced in time to have the electric trams running between Annesley Bridge and Dollymount by the end of the present year. Up to the present the company have no powers enabling them to employ electric traction within the city, and consequently horses must continue to draw the cars from Nelson's Pillar until they get extended powers whereby they can use electricity from start to finish of the line.

The Mumbles Railway.—Following the offer from a powerful syndicate to acquire, on terms which could not be entertained, the Mumbles Railway, and to adopt electricity as the motor power, a fresh offer (says the *South Wales Daily News*) has been received from the same syndicate which embraces terms that have led the chairman of the Mumbles Railway Company to have conferences with the syndicate. The negotiations have now reached a phase which makes business not unlikely, but owing to the absence abroad of one of the leading members of the syndicate, nothing definite can be settled till November.

An Indicating Bell Push.—Mr. J. W. Creasey, of Fife-road, Kingston-on-Thames, has forwarded to us particulars of a new indicating bell push he is putting on the market. The push button is placed out of the centre of the cover, and on the opposite side is a disc which is oscillated when a current passes. This is effected by placing a magnetic needle at the back of the indicating disc, which is over a small electromagnet. The current to the bell passes round the few turns of wire encircling the core, and hence the disc oscillates as the bell rings. Thus the operator always knows whether he has rung the bell or not.

Davies Motor Company, Limited.—This Company has been started, with a capital of £160,000 in £1 shares, to adopt and carry into effect an agreement between the Alternate-Current Ellbro Motor Syndicate, Limited, and the Company for the acquisition of certain patents and other rights belonging to the syndicate, to develop and turn to account the same, and to carry on business as manufacturers of, and dealers in, alternate-current motors, and to carry on business as electrical and general engineers, light and power contractors, electricians, electrical manufacturers, makers of dynamos, motors, apparatus, and fittings, to construct and maintain rail and tram roads, etc.

Brighouse.—The sub-committee of the Gas Committee, appointed to consider the question of purchasing the electric lighting plant from Mr. A. B. Brook, report that they have had the plant valued by Mr. Blakey, of Bradford, and they have made Mr. Brook an offer of £1 535 for the plant, which has been accepted. They recommend that the plant be purchased for this amount, Mr. Brook to work the plant at his own risk till the license to supply electricity has been obtained by the Corporation from the Board of Trade, and that afterwards the Corporation take over the plant and pay Mr. Brook £100 per annum for the use of the overhead wires till such time as the Corporation can lay them underground. The Gas Committee have recommended the report to the Council for adoption.

Hove (Brighton).—A letter was read at the meeting of the Urban District Council from the Hove Electric Lighting Company stating they were informed that the Council had acceded to a proposal made by the owners of the Stanford Estate that this company be permitted to extend their electric lighting mains from the top of Wilbury-road across from the Hove boundary to the corner of the Stanford Estate in Upper Shoreham-road on condition that they entered into an agreement with the Council to remove the mains if and when called upon to do so. They, therefore, enclosed a draft agreement, adding that if it was approved they would send a copy executed by the company, and ask the Council to execute a duplicate on their part. The agreement was approved, subject to a few minor alterations.

Fort William.—The streets in Fort William have just been lighted by electricity, supplied by the Fort William Electric Lighting Company, Limited. So far only two arc-light pillars of 1,000 c.p. each have been erected, but it is expected that the other four for the main street will be in position in little more than a week. Two of these latter pillars will contain drinking fountains of an ornamental description, and are to be placed in Gordon-square and Fraser-square respectively. In addition to the arc lights there are to be over 60 16-c.p. incandescent electric lamps, all of which will be in working order in about a fortnight. The light given by the arc pillars already erected was of the most satisfactory description. Experiments in cooking and heating by electricity were also made on Saturday night, and the results obtained gave entire satisfaction. The electric lighting company are also to give an exhibition of electricity as a motive power applied to farm implements at the Lochaber Agricultural Show on the 15th prox. Besides a number of private houses and hotels in Fort William, the Episcopalian and Catholic Churches have already been lighted by electricity.

Appointment Vacant. — The Hammersmith Vestry invite applications for the appointment of resident engineer, to supervise, under the consulting engineer, the erection of the electric lighting plant and other works in connection therewith, and afterwards to undertake the management and control of the electric light department. The person appointed will be required to reside in

Digitized by Google

the parish, and must give the whole of his time to the duties of his appointment. Applicants must have a thorough mechanical training, and be well versed in the erection and running of boilers, engines, and electrical machinery. Salary £200 per annum during the erection of the works, etc., to be increased to £250 when the installation is completed and in working order. Forms, upon which applicants must send in their applications, may be had from Mr. W. P. Cockburn, vestry clerk, Temporary Offices, 57, Fulham Palace-road, Hammersmith, and any further information may be obtained upon application to Mr. A. H Preece, consulting engineer, 39, Victoria-street, Westminster. Applications, marked on the outside "Resident Engineer," must reach the vestry clerk by 4 p.m. on September 2. Canvassing both personal or otherwise will disqualify candidates. Applicants will not be required to attend, and no travelling or other expenses will be allowed.

Manchester.—The suburban authorities in the vicinity of Manchester, particularly those having jurisdiction on the south and south-western sides, are just now considering proposals for the establishment of the electric light within their several areas. The Corporation are desirous, it is understood, to extend their electric light system into the suburbs, and with this object in view the Gas and Electric Lighting Committee propose that a conference of the local authorities of Moss Side, Withington, Stretford, and Levenshulme should be held. We understand that a company has been formed, under the title of the South Manchester Electric Supply Company, Limited, and has offered to supply the Moss Side district with the electric current for lighting purposes. A powerful syndicate of capitalists have also undertaken not only to give the electric light to residents in the Manchester suburbs, but to provide an extensive system of electric tramways. This syndicate, acting in conjunction with Messrs. Andrews and Butterworth, architects and surveyors, of this city, and Mr. Joseph Sampson, of Albert-square, solicitor, have already approached some of the local authorities and intend in the course of the next few days to have interviews with others, with the object of arranging terms for installing the electric light and providing electric haulage for tramways.

Southport.—The demand for the electric light not having been taken up to the extent anticipated, the Electricity Committee arranged an exhibition of alternating-current arc lamps, motors, etc., which is being held this week. The exhibition included two lamps of 15 amperes, or 1,200 c p., by the German Electrical Company; two Helios lamps of the same power running parallel off a transformer; two Lewis 12-ampere lamps by Messrs. Fowler, of Leeds, running on the reacting system; two more of the German Electrical Company's lamps, of 900 c.p., running in series, and shown by Messrs. Calvert and Co., of Manchester; also two of Crompton's, and two from the Brush Company, all of 1,200 c.p., running in series. These arc lamps differ from those at present in the streets, which are supplied with a rectified current, whereas those on view were supplied direct from the mains. In addition to the arc lamps there were a number of small motors in use, two of them driving sewing-machines, while a third, of ½ h.p., ran unharnessed. A couple of fans for ventilating purposes, a number of heaters, an electrically-heated kettle, and a working diagram of a Raworth-Brush steam-engine were also included in the exhibition. The arrangements were in the hands of the borough electrical engineer, Mr. Charles D. Taite. Current is now being supplied by the Corporation for motors and heating apparatus at 4d. per unit.

Llandudno.—At the meeting of the Urban District Council the surveyor submitted three tracings showing suggested alternative sites for the erection of electric light station and destructor works, also showing in conjunction therewith the proposed siding to the gasworks and temporary road, and the enclosing of an additional three acres of land. The committee adopted scheme No. 2, which shows the electric light station and destructor at the rear of the gasworks. The committee were of opinion that it would be advisable to procure a quantity of land, in addition to the land above mentioned on the north-east side of the gasworks, amounting to three acres or thereabouts, and they requested the surveyor to prepare an amended plan and forward a copy thereof to the Mostyn Estate and ask for terms for the purchase or lease of the land in question. On the suggestion of the engineer, it was decided to ask Mr. A. H. Preece and Mr. Deas to meet the chairman of this committee and the engineer to the Council to discuss and settle various questions connected with the combined scheme. The engineer reported that he had considered the question of destructor chimney, and estimated the approximate cost at £1,100 to £1,200. He had also estimated that the cost of carrying a shaft up the Bryniau Hill as suggested would amount to about £3,000. The committee considered that the latter course was out of the question.

Brighton.—The Lighting Committee reported at the Town Council meeting that at a meeting of the Lighting Committee on August 10 the surveyor stated that the lamps in Sussex square were of an old pattern and not suitable for electric lighting purposes. He was instructed to replace the lamp pillars with others which he had in stock. The town clerk submitted a letter he had received from Callender's Bitumen Telegraph and Waterproof Company, Limited, stating that their business had been transferred to Callender's Cable and Construction Company, Limited. The committee recommended the Council to consent to the transfer of the contract, dated July 23 last, for the supply of armoured cable during the 12 months ending May 1, 1897, subject to the sureties named in the bond for the performance of the contract entering into a fresh bond to secure the performance of the contract by Callender's Cable and Construction Company, Limited. The manager was granted one month's leave of absence. The town clerk reported that Messrs. Reed and Son had applied for an extension of time for the delivery of the electric light bracket posts under their contract. An extension of time to August 15 for the delivery of the first 20 bracket posts, the remainder to be delivered at the rate of five per week, was recommended. The manager reported, suggesting that tenders be invited for the purchase of old scrap iron and scrap cable ends at the electricity works, and the suggestion was approved of and ordered to be acted upon. These proceedings were confirmed.

White Lead Admixtures.—We have received the following circular letter from Mr. Kenric B. Murray, secretary of the London Chamber of Commerce: "I am directed to inform you that the leading white lead corroders have resolved to support the action taken by this Chamber in this matter as far as lies in their power, and to induce their friends to adopt the same course. With this view they have decided (1) to discontinue the use of the term 'best' as a trade description for admixtures of white lead, believing it to be a false and misleading description within the meaning of the Merchandise Marks Acts, 1887 and 1891; (2) to brand or stencil all packages, wooden or iron, containing white lead admixtures with the word 'reduced'; and (3) to invoice all white lead admixtures as 'reduced white lead.' These measures are proposed in the interests of the reputation of English trade, and will, I feel sure, meet with universal support. The responsibility for the illegal and dishonest practice of selling reduced white lead as 'genuine' (which might be unjustly fastened upon the manufacturer, in the event of his having supplied reduced white lead without brand or mark, and the packages being subsequently branded or marked by a second party 'genuine') will, it is hoped, by the means proposed, be brought home to any who are guilty of the dishonest practice. These resolutions will come into force and take effect on and after October 1 next, so that sufficient time is thus afforded to all parties to make any necessary arrangements as to alterations in trade lists, brands, marks, etc., consequent upon the decision intimated in this letter."

Canterbury.—A special meeting of the Corporation has been held for the purpose of considering the minutes of the Whole House Committee meeting on the question of the inclusion of the proposed dust destructor with the scheme of the electric lighting works. The town clerk read the minute of the committee meeting as follows: "The committee recommended that the question of the site for the electric light works and dust destructor, on the advice of the town clerk, that the Millers' Field is not available for the purpose, be reconsidered by the committee and that they report." Councillor Harris moved that the words "and dust destructor" be omitted from the minute. This was seconded by Alderman Wells. Councillor Lukey was very sorry that they had submitted that amendment. It had been understood throughout by the members, or a majority of them, that the dust destructor should run in double harness with the electric light. The amendment now proposed would narrow the matter down to the smallest degree, and was one that he for one did not approve of. The dust destructor was advocated with a view to saving in producing the electric light. He felt that was not the proper time to have the amendment so ably put by Councillor Harris before them. He trusted that that Court would let their original idea stand, and decide to let the electric light and dust destructor, as arranged in the meeting, go together. Councillor Horsley agreed with Councillor Harris that the site that suited one purpose might not suit the other. Could they not alter the wording of the minute so that the committee, while reconsidering the matter of a site for the electric light, might also be on the look out for one for the dust destructor at the same time? The chairman, after some further discussion had taken place, put the amendment, which was lost by eleven votes to seven. The original minute was then put and carried with only two dissentients.

Edinburgh.—The revenue of the electric lighting undertaking for the year to May 31 was £25,862, and the expenditure £11,590, to which is added depreciation written off capital £6,329, the balance carried to profit and loss account being £7,943. The committee had to meet the following requirements: interest on loans, £4 246; sinking fund, £1,316; leaving a surplus on the year's operations of £2,381, which is transferred to the credit of the gas account. In view of the favourable balance, the committee have approved of the recommendation by the special sub-committee that a reduction in the price of current, on a scale which necessitates a new method of charging, should take effect as from and after June 1 last. This new method, the committee anticipate, will increase the popularity and use of the electric light. Indicators will be placed in consumers' premises to ascertain the greatest quantity of electricity taken at any one time during the year, which quantity is called the "maximum demand." To customers who use in the year the maximum demand for 365 hours only, being an average of one hour per day, or any lesser quantity, the price charged will be at same rate as at present—viz., 6d. per Board of Trade unit; but for all electric energy used over this quantity that the charge will be at the rate of 4d. per Board of Trade unit. The committee have also approved of the recommendation made by the Special Sub-Committee that the charge for meter hire be discontinued from and after September 1, and that so soon as the current for the supply of street lamps is taken from Waterloo street station, instead of John-street station, the price charged for each lamp should be reduced from £26 to £20 per annum. The number of consumers at May 31 last was 855, being an increase of 269 over the number at same date last year. The quantity of electricity sold during the past year to private consumers, irrespective of public lighting, was 866,606 Board of Trade units, being an increase of 24·11 per cent.

Digitized by Google

Great Horton.—An enthusiastic public meeting was held a few days ago to consider the desirability of a tramway being laid to the town, and a resolution was passed urging the Bradford Town Council to take immediate steps to bring this about. Mr. W. C Dixon, chairman of the Gas and Electricity Supply Committee of the Bradford Corporation, said that they had at their electricity works a great amount of electric power standing idle during the daytime, which would bring all the people to Great Horton who wanted to come, and without any cost to the Corporation. People were now getting their eyes opened to what electricity could do, and orders were being received for motors for all kinds of driving power. The committee were putting down a gigantic station, which would be one of the finest in England. Bradford had been the first municipal borough to take up electric lighting, but they had let other places outstrip them. Alluding to the tramcars of America, which were both run and lighted by electricity, he said that the electric cars in Boston carried more passengers than all the locomotives in the State of Massachusetts put together. All over the world the electric cars were beating all the other kinds of cars, and he took it as a settled thing that if they were to have trams run to Great Horton they would be run by electricity. He believed the Labour members of the Council were afraid that if a tramway were run to Great Horton and it didn't pay this would jeopardise the municipalisation of the tramways six years hence. He did not agree with that, but considered that they ought to try an experimental line before taking in hand a large scheme. At a subsequent meeting of the Bradford Corporation it was decided to apply for parliamentary powers to construct lines along Bolton-road and also to Great Horton. With regard to the Great Horton scheme representatives of the British Wire Company demonstrated to the committee the utility of their system of laying underground electric wires for the running of trams. and Mr. Cox, the borough engineer, was instructed to prepare plans showing the length of cable that would be required.

Mitchelstown.—Now the area of taxation for the electric light scheme comes to be defined the Guardians are meeting with some objections. The valuation of the town is £2,900, but by taking in some extra lands, as the Board wished to do, the valuation would be increased to £3,500. The following letters were read at the last meeting: "Flemingstown, August 20, 1896. Sir,—I hereby give you notice, as clerk of Mitchelstown Union, that I will not consent to have my agricultural holding at Brigoun included in the area of taxation for the Mitchelstown electric lighting, but will oppose any further increase of rates on my lands to the utmost of my power. I consider it enough to have to pay the increased rate for electric lighting on my house property in town. My cattle can graze without electric light, as they have always done. When I wanted to obtain what would be of use to my cattle—viz., water—I could not get it, though I offered to pay the Guardians as much as any other person for it.—Yours, etc., ELLEN COUGHLAN." "The Square, Mitchelstown, August 9, 1896. Sir,—I have been informed that at last meeting of the Board of Guardians here the area of taxation for electric lighting the town was under consideration, and, I understand, was adopted by them. Now I am told that the original area was altered unknown to many of the Lighting Committee immediately before the Board meeting, and without consulting the ratepayers, and that a piece of land, the valuation of which is £14, which I hold outside the town, at Ballinvullen was smuggled into the area at the last moment. There is no residence on the land. In case this scheme for the lighting of the town becomes law I shall have to pay in the town alone taxes on a valuation of £63. 10s., but if this land is added on unknown to me, I must protest against such an unjust proceeding. Owing to the manner in which the committee was formed, too much confidence should not be placed in it as the members were elected by two factions and large ratepayers excluded. It is my opinion that no sanction should be given to their recommendations until an experienced engineer examines and approves of the number of lamps proposed to be erected as well as the available water supply.—I am, Sir, yours, etc., EDWARD WALSH." After some discussion it was decided that the consideration of the area of taxation should be referred to a committee.

Cardiff.—At a meeting of the Chamber of Commerce it was reported that Mr. Gaine, general manager of the National Telephone Company, had recently had an interview with Messrs. John Gunn, H. J. Simpson, J. Andrews, and G. N. Kestell on the subject of amalgamation of the telephonic systems. Those representing the Chamber urged that the systems should be acquired by the Government, and that in the meantime the subscribers to the two systems in this district should be allowed to communicate with each other the same as was done in certain areas. Mr. Gaine had told them that the Government had acted rather unfairly towards the National Company. In Cardiff and Newcastle the Government had encroached upon their preserves, and must be looked upon as competitors, and the question of the Government acquiring the National Telephone Company's system was one with which he could not deal. As to the using of both systems, he pointed out that the National Company had 800 subscribers in the Cardiff district, while the Government had only 150, and such an arrangement would certainly not be equitable or fair to the former. The Chairman said it was a fact, as stated by Mr. Gaine, that it was only at Cardiff and Newcastle that the Government competed with the National Company, and explained that the latter had a capital of about two millions sterling at stake. The directors were, therefore, bound to study the interests of the shareholders. Mr. Gaine had, however, promised to do all in his power to remove grievances complained of by subscribers, and had expressed himself in favour of Barry being included in the Cardiff area, although his directors were not agreed as to that. If Barry were included, subscribers doing business there would save a considerable amount of money annually. Mr Coward and others complained that since the Government had got possession of the trunk lines communication had been worse than before, Mr. Coward stating that the delay in getting through and the cutting off of the connection too soon was so great that he decided to give it up at the end of the year. On the motion of Mr. W. Lester Jones, seconded by Mr. J. Andrews, the following resolution was unanimously agreed to: "That in the opinion of this Chamber, Barry should be declared within the Cardiff area of the National Telephone Company, inasmuch as Barry is in the Customs port of Cardiff, and the business there is almost wholly conducted from Cardiff."

Hastings.—A Local Government Board enquiry has been held by Mr. Rienzi Walton into the application of the Town Council to borrow £7,560 for purposes of electric lighting. The Town Clerk stated that about the year 1890 they obtained a provisional order for public lighting purposes, and it was not thought desirable to get a public lighting order. They had not availed themselves of the order up to the present time, it having been done by contract with the local electric lighting company—this contract would expire in less than a year, in July, 1897—the company lighting the front line and also the various public buildings, such as the Town Hall and Brassey Institute. They paid £27 for 52 lamps along the front, and the other was paid by meter. The Corporation had been in negotiation with the company, as the end of the contract was approaching, as to what the company would be prepared to do, and they had received an intimation that the present system did not answer the purposes of the company, and if it were continued, the price would be considerably enhanced. A sub-committee had gone very carefully into the matter, and had come to the conclusion that it would be much better if they (the Council) had an electric lighting system of their own, and by so doing there would be a considerable saving to the ratepayers. The Council now asked the Local Government Board's sanction to borrow this sum to make alterations to buildings and for plant, and for the cost of various appliances which they would have to take over from the company under the existing contract. A special plant had to be provided for public lighting purposes. They had been in communication with the Board of Trade, but had not received any intimation that they approved of the system of supply. In reply to the inspector, Mr. P. H. Palmer (the surveyor) said at present the Council only intended to light the 52 lamps along the front line from the end of Marina to the fish market, a distance of about 2½ miles. The public station they acquired some 40 years ago, and the premises covered an area of about 1,070 square yards. Mr. Palmer explained the alterations that would take place, and said there would be two boilers of 154 h.p., three steam dynamos, and the necessary instruments. The arc lamps were supposed to be of 2,000 c.p. each, and each dynamo was capable of supplying 35 lamps. The steam-pipes, etc., were provided for in the estimate. They did not intend to do any private lighting, though they would supply the public buildings. The estimates provided for the extension of street-lighting. There was no opposition to the loan.

Lambeth.—The Vestry having decided, with the consent of the Board of Trade, to transfer their provisional order to Mr. C. W. Sax, have given public notice of their intention. The transfer contains the following provisions: (*a*) That the said transfer will comprise the whole of the area in respect of which the said order was made, such area being the whole of the parish of Lambeth, with the exceptions set out in the first schedule to the said order. (*b*) That the said transfer will be for the whole period covered by the said order, with an option to the Vestry to repurchase the whole undertaking on giving 12 months' notice at the following periods—viz. (1) at the end of 21 years on payment to the transferee of 25 per cent. over the price that would be fixed under the statutory compulsory power of purchase, provided for by the Electric Lighting Act, 1888; (2) at the end of 31 years on payment of the statutory compulsory terms without any addition thereto. (*c*) That the pecuniary consideration for the intended transfer is to be the payment of £1,000 to cover the expenses actually incurred by the Vestry in obtaining the order, and the expenses incurred thereunder, and in connection with the transfer of the order. (*d*) That the price to be charged by the transferee for a supply of energy shall be 6d. per Board of Trade unit, such price to be reduced by not less than ¼d. per unit for each 1 per cent. of dividend declared over 6 per cent. on the whole ordinary stock or share capital of the undertaking, such 6 per cent. to be on an average of years. (*c*) That the transferee shall deposit with the Vestry the sum of £100 to cover the cost of works, under Clause 14 of the order, and pay expenses of work from time to time. (*f*) That the transferee will supply energy for lighting the public lamps on the Vestry undertaking to take the energy for three years, the price to be settled by agreement. and in case of difference by arbitration. (*g*) That the transferee shall not consent to the revocation of the order without the approval of the Vestry, but may transfer the undertaking upon terms to be approved by the Vestry, but no part of any premium to be claimed by the Vestry. (*h*) That the transferee shall deposit £5,000 with the Vestry as a guarantee for the completion of the compulsory electric work within two years from the date of the transfer, the Vestry to pay to the transferee 2 per cent. interest, but the deposit to be forfeited to the Vestry if the works are not completed within three years. (*j*) That the transferee shall supply the electric current free of charge for 25 public arc lamps to be erected by the Vestry. (*k*) That the transferee shall erect and maintain a refuse

Digitized by Google

destructor, and cremate thereby the whole of the dustbin refuse to be supplied by the Vestry, the Vestry undertaking to deliver the dustbin refuse of at least one-half of the area of the parish, and to pay to the transferee 11½d. per ton for the refuse delivered, the destructor to be considered as part of the undertaking if the option to purchase is exercised by the Vestry. (*l*) That Sections 9, 31, 55, 56, 57, and 72 of the order shall not apply to the transferee.

Leeds.—In connection with the new electric tramways, which the Corporation propose to work between Roundhay Park and Kirkstall, a commencement has been made with the relaying of the lines on the Kirkstall section. A large staff of men are engaged in taking up one track, the traffic in the meantime being conducted on the other line, which, with the view of meeting the public convenience, has been left undisturbed. At the other end of the electric section considerable progress has been made with the construction of the tramlines from the new entrance to Roundhay Park to the Canal Gardens, and should no unforeseen circumstances arise there is every reason to hope that in the course of a few weeks the road will be finished, and pending the completion of the electric equipment steam cars will probably be run to the Canal Gardens. The Tramways Sub-Committee of the Highways Committee at their last meeting had before them the applications for the position of clerk of works for the electrical equipment of the tramway. The applicants numbered 35, and the committee selected the following five to appear before them at a meeting to be held next week: Mr. H. G. Sprague, Dublin; Mr. Frank B Lea, London; Mr. John Burbridge, Leeds (late manager for the Thomson-Houston Company on the Roundhay section); Mr. Ernest K. Scott, Wolverhampton; and Mr. C. F. F. Smith, Blackpool. The salary will be fixed when the appointment is made. The application from the tramway servants for an increase in their wages was also brought before the committee, and it was decided to hold a special meeting to consider the matter. At the meeting of the Highways Committee of the Corporation the members spent several hours in visiting various parts of the city where it has been suggested that tramways should be laid. It was ultimately decided to place several routes before the City Council, and recommend that application be made for the necessary powers of construction The new lines which it was decided to recommend are as follows: from Tong-road, near the Crown Inn, along Oldfield-lane and Upper Wortley-road to the Star, where the present Wortley system terminates; from Wellington-street, down Aire-street to the Cattle Market, by way of Whitehall-road and Gelderd-road; from the junction of Dewsbury road and Meadow-road, along Meadow-road, Beeston-road, and Beeston-hill, to near the school at the end of Town street, Beeston; from the junction of Beeston-road and Elland road for some distance up Elland-road; from Dewsbury-road along a new road which it is intended to form; from Dewsbury-road to Moor-road, Hunslet, along Moor-road to Hunslet Carr, Balm-road, and Church-street, to join the Hunslet tramway in Hunslet Low-road, from New Market-street along Vicar-lane to North street, when the contemplated widening has been carried out; along Infirmary-street, East-parade, Calverley-street, Great George-street, Clarendon-road, Moorland-road, Hyde Park-road, to Hyde Park-corner; along Park-lane from East-parade to Burley-street, Burley road, Cardigan-road, St. Michael's-road, joining the Headingley tramway at the Oak; from the bottom of Victoria-road, Headingley, down Woodhouse-street and Cambridge-road, joining the Meanwood tramway. It was also decided to recommend the City Council to apply for power to extend the tramway, which has been authorised to be carried to near the New Inn, Tong-road, to extend it to some little distance above that point; also to continue the authorised tramway terminating at the New Inn, Dewsbury-road, to the entrance to Cross Flatts Park. It was reported to the committee that under the Act which received Royal assent in July last, the Corporation obtained powers to construct the following tramways: Prince's avenue to Roundhay Park; bottom of York-road to Victoria avenue; Meanwood-road, from Buslingthorpe-lane to Monkbridge-road; Tong-road, from the present termination to near the New Inn; Whingate, from Tong-road to Town street, Armley; Armley-road, from Wellington-road to near the bottom of Branch-road, Armley; Abbey-road, Kirkstall, from present termination to Kirkstall Abbey; Meadow-lane and Dewsbury-road, from Bridge End to near the New Inn. Revived powers under the Act of 1888 had been obtained for the construction of a tramway along Beckett-street, Burmantofts-street, and York street to its junction with Kirkgate.

Glasgow.—With a view to the ultimate adoption of a system of lighting their trains by electricity, the Caledonian Railway Company have had an experimental train fitted up in their works at St. Rollox, and a trial has been made on the new Underground Central Railway. The train consists of seven six-wheeled carriages—two first-class, three third, and two third brakes. The system now being experimented with is that of Messrs. J. Stone and Co., which has been previously described in these columns. Each vehicle carries its own generating plant, the motion of the carriage producing the electricity, and storing it in an accumulator, which automatically comes into action when the train slackens speed or stops at stations. The dynamo, which is driven by means of a light strap or belt direct from a pulley on the axle, is suspended from the underframe of the carriage in such a manner that absolutely none of the vibration of the axle is transmitted to it. However the speed of the axle may vary, the dynamo always runs at a uniform rate, and always produces the same amount of electricity. A mechanical governor automatically connects the dynamo to a small accumulator when the train is in motion, and the lamps then take their current direct from the accumulator. On the train stopping the supply is maintained to the lamps from the accumulator, which has a storage of fully seven hours. Each carriage is provided with a switch, so arranged that the light can be fully or partially on or altogether cut off. There are two lamps in each compartment. Before the system is further extended it will be given a thorough practical trial on the Central Railway between Rutherglen and Maryhill. At the meeting of the Corporation Mr. R M. Mitchell moved the approval of the minutes of the Gas and Electric Lighting Committee. The minutes contained a recommendation, already published, to the effect that a new method of charging for electric light should be adopted—viz., to customers who use in the year the maximum demand for 365 hours only, being an average of one hour per day, or any lesser quantity, the price charged will be the same as at present—viz., 6d. per Board of Trade unit; but for all electric energy used over this quantity the charge will be at the rate of 4d. per Board of Trade unit. Mr. Ferguson wished to know the relative cost of gas and electric light. Mr. Mitchell said he understood that the electric light cost about 2½ times more than gas. The Chairman said his experience was that the cost was a little more. Mr. Ferguson asked whether a current of 500 volts was dangerous. Mr. Mitchell said he understood there was no danger with such a current. Mr. Primrose congratulated the committee on the financial statement submitted. It showed gratifying progress in the development of the new light. He noted with special gratification the recommendation of the committee to adopt the new system of charging. No one who had witnessed the operation of the system in such a town as Brighton but must be satisfied that it would be an advantage to the consumers. Mr. Fife, in moving the adoption of the report of the committee, said that it must be a source of gratification to all concerned that the year's work had resulted in favourable financial balances. In the electric lighting department the committee felt satisfied that they were working on good sound financial lines, and these had now been verified by the results of the last year's work, turning a deficiency of last year, £1,527, into a surplus this year of £2,580, and this after providing amply and fairly for depreciation and sinking fund. The committee believed they had in the Waterloo-street works one of the best electric lighting stations for its size in the country. In order to develop its utmost producing powers the committee, after very careful investigation by a sub-committee, under the convenership of Bailie Burt, recommended a change in the mode of charges—first, to abolish the charge for meter rents, a saving of some £300 per annum to the consumers; second, that the price be 6d. per unit for the first hour of each day and 4d. per unit for every hour thereafter, thus meeting the case of those who could use the current for a longer time, and which would enable the plant to be worked with more regularity and economy. They asked that this, the Brighton system, should have a fair trial, as, so far as could be judged, it might lead to further reductions in the future. The Watching and Lighting Committee must also be gratified with the recommendation of the committee to reduce the price per lamp from £26 to £20, the lowest in the kingdom for a continuous light of the power now furnished. Bailie Burt said they ought to encourage the use of electric motors during the day; and as they understood they were in use from eight to ten hours per day, the man who kept a motor going that time would get the benefit of the reduction. With reference to additional generating stations and mains, so as to supply the whole city, the committee did not feel ready to bring up a report on such an important subject. He felt that they had been set back a little by the delay in settling the question of electric tram way traction. The committee felt that should the city adopt some mode of electric traction they would present a solution of this electric lighting question that could not be found under existing circumstances. He had not the slightest fear of gas and electric light coming into rivalry. If they supplied gas at a cheap rate, they might have the majority of the citizens using it instead of coal for heating and lighting purposes. He was glad that the Council had adopted the report without any very serious objection because he felt it was some compensation to the committee for the time and labour they had expended upon it. He was satisfied that they were really in the front so far as their system of electric lighting was concerned, more especially as the Board of Trade had raised the pressure to 500 volts, Mr. Ferguson had asked if 500 volts was dangerous, but the Board of Trade did not consider it dangerous, or they would not have allowed the pressure to be raised without the wires being specially insulated. If the electric lighting was to be developed, he felt that the Council would have to face a very large extension of the generating station. The question for the committee next year would be whether they should acquire more ground and extend the station in Waterloo street, or institute small stations throughout the city. The settlement of the tramway traction question would to a very large extent influence the committee in their decision. Mr. Ferguson suggested that, instead of borrowing on interest, notes on the security of the rates should be issued. He observed that the sum carried forward from the electric lighting account had been transferred to the gas account. He did not think this was right financing. The balance should have gone to the development of the electric light. Mr. Fife said it certainly did seem anomalous. But the accounts must be kept in accordance with the provisional order. The gas department during the three previous years bore the deficiency on the electric lighting account. The first year that deficiency amounted to £1,773, the second to £607. 3s., and the third to £1,527, and this was the first sum that had been paid towards that deficit. When they had squared the account they might rest assured that the consumers of electric light would receive the full benefit.

PROVISIONAL PATENTS, 1896.

August 17.

18191. Improvements in galvanic batteries. Julius Brandt, 6, Lord-street, Liverpool.

18196. Improvements in the construction of tubes and tubular electric conductors. Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

18205. Improvements in electrically-operated carillons. Edgar Herman Carqueville, 45, Southampton buildings, Chancery-lane, London.

18220. An improved meter or apparatus for registering the consumption of alternating electric current. James Yate Johnson, 47, Lincoln's-inn-fields, London. (Messrs Hartmann and Braun, Germany.) (Complete specification.)

August 18.

18249. An improvement in the preparation of filaments for glow lamps. William Samuel Tothill Martin and Henri Weymersch, "Lyncote," Green-lane, East Dulwich, London.

18273. Improvements in dynamo-electric machines. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Robert Lundell and Edward Hibberd Johnson, United States.) (Complete specification.)

18312. Improvements in induction telegraphy. Sydney Evershed, 1, Queen Victoria-street, London.

18317. A new or improved device for use in connection with electric railways. Frederick Carleton Esmond, Norfolk House, Norfolk-street, London.

August 19

18319. A new or improved electric hand lamp for general or special purposes. Arthur John Westmancott, 22, Alfred-street, Islington, London.

18326. Improved preparations for accumulator plates. Henri Weymersch, 58 Oakhurst grove, East Dulwich, London.

18364. An improved electric motor or dynamo-electric machine. John Thomas Knowles, of the firm of D. Young and Co., 11, Southampton-buildings, Chancery-lane, London. (James Harold de Thierry, Italy.)

18408. Improvements in the production of electric light. Joseph Dobson, 37, Chancery-lane, London.

August 20.

18420. The practical application of the electric light to bicycles, tricycles, carriages, and all motorcars. Frederick Ritchie, 113, Burdett road, Bow, London.

18454. Improvements in incandescent electric lamps. Jan Meines Huisman and Henry Charles Gover, 62, St. Vincent street, Glasgow.

18464. Improvement in electric gas-lighters. Erik Orling, 163, Queen Victoria-street, London. (Date applied for under Patents, etc., Act, 1883 Sec 103, 23rd April, 1896, being date of application in Sweden.)

18469. Improved method of and means for attaching telegraph and other wires to insulators. George Middleton, 55, Chancery-lane, London

18479. Improvements in the manufacture of electric cables. Mervyn Joseph Pius O Gorman, 24, Southampton-buildings, Chancery-lane, London.

18485. Improvements in acid-proof electrical non-conducting articles and composition therefor William Morison, 119, West Forty-second street, New York.

18497. Improvements in electrical measuring and signalling instruments. Herbert Watson Sullivan, 40, Chancery-lane, London.

August 21

18508. Improvements in arc lamps. Joseph Edmondson, Penny Bank-chambers, Halifax.

18522. Improvements in automatic signals William Edward Langdon and William Llewellyn Preece, Midland Railway, Derby.

18537. Apparatus intended to determine the quantity of metal which a galvanoplastic bath should deposit on the object treated. Joseph Ducot, 8, Rue des Princes, Brussels

18549. Improvements in or relating to electrical primary batteries. Joseph Bruce Whittemore, 36 Chancery lane, London. (Complete specification.)

18570. Improvements in electric batteries. Fritz Dannert, 40 Chancery-lane, London. (Complete specification.)

August 22.

18580. Improvements in and relating to electrical ceiling roses, switches, and the like. William McGeoch, 96, Buchanan-street, Glasgow.

18593. An improvement in electrical apparatus. John Forrest Kelly, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18628. Incandescence body for electrical glow lamps and process of manufacture of the said body. Josef Franz Bachmann, Adolf Vogt, Carl Camillo Wiener, Josef Kirchner, and Albert König, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18627. A depolarised galvanic element. Albrecht Heil, 28, Southampton-buildings, Chancery-lane, London.

18632. Improvements in holders for incandescence electric lamps, also applicable to the holding of the shades or reflectors thereof. Hugo Hirst and George Edwin Fletcher, 73, St. Stephen's-road, Upton Park, London.

18648. Improvements in electrical storage or secondary batteries. Rankin Kennedy, 33, Gladstone-street, Bradford.

18649. A new or improved recording electricity meter. Rankin Kennedy, 33, Gladstone-street, Bradford.

18651. Improvements in commutator brushes for dynamo-electric machines or electric motors. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London (Robert Lundell, United States.) (Complete specification.)

18652. Improvements relating to electric railways. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Robert Lundell) United States.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1895.

14493. Electromotors and dynamos. Hollick and Hollick.

15868 Arc lamps Andrews.

16019 Incandescent electric lamps and their holders and fittings. Johnson. (Swan.)

17505 Electrodes Hoepfner.

17741. Device for indicating the duration of telephonic conversations Van Kerckhove.

17871. Compositions for protecting ships' bottoms against fouling, preserving wood, and shielding submarine electric cables from penetration by toredo worms. Gunn.

18369. Elect ic locomotives. Amen.

1896.

11441. Electric arc lamps. Adams.

14005. Apparatus for automatically closing and opening by electrical agency the barriers of railway level crossings. Van der Valk.

14187. Portable electric drill. Holmes and Siemens Bros. and Co., Limited.

NOTES.

American Institute of Electrical Engineers.—We have to acknowledge the receipt of No. 4 of vol. xiii. of the *Transactions* of this society.

Fire.—Mr. A. Vaughan Stevens's house at Harpenden has been burnt down. The cause of the fire has been ascribed to the heating and fusing of the wires used for the electric lighting of the building, but on what grounds we do not know. The family were away, and there was no one in the house at the time except the housekeeper.

The Midland Engineers.—The annual meeting of the Chesterfield and Midland Counties Institution of Engineers was held last week at the Stephenson Memorial Hall, Chesterfield. The new president for the year is Mr. M. H. Mills. The report showed that 25 new members had been admitted during the year, as against 28 the year before, the total membership being 349.

Photographic Society.—The forty-first annual exhibition of the Royal Photographic Society will open to the public on Monday, September 28. On the Saturday before there will be a private view, and in the evening a conversazione at which the president, Captain W. de W. Abney, C.B., F.R.S., and the council will receive the fellows, members, and their friends.

Whitworth Scholars.—The Department of Science and Art have issued the list of candidates successful in the competition for the Whitworth scholarships and exhibitions in 1896. The following secure scholarships of the value of £125 a year each, tenable for three years: Frederick C. Lea, Crewe; William A. Taylor, Crewe; Henry T. Davidge, London; John W. Hinchley, Lincoln.

Personal.—Mr. J. H. Belcher, F.C.S., who has been head master of the science branch of the School of Science and Art at Lincoln for over eight years, has been appointed headmaster of the Municipal Technical Institute and School of Art at Coventry. The committee of the Lincoln school has appointed Mr. A. E. Collis to be head of a new engineering department at the school. Mr. Clarence H. Creasey, a first-class honours man, and Queen's medallist, has been appointed instructor in chemistry.

Petroleum.—A vaporising petroleum lamp used in some building operations at Brompton exploded last week and killed a workman. At the inquest Mr. Gibson, who represented the London County Council, said this was the third case of the kind that had come under his notice in two years, and two had terminated fatally. The jury returned a verdict of accidental death, and added a rider to the effect that in future some person having a thorough knowledge of the lamps should be placed in charge of them.

Telephone Switchboards.—Mr. Dane Sinclair's paper at the Institution of Electrical Engineers on the subject of the working of a telephone exchange has been translated and published in full by the *Journal Télégraphique*, which is the organ of the Bureau International. In reference to the readiness of French writers to adopt foreign expressions, it may be noted that "jack" occurs once between inverted commas, after which both jack and spring-jack take their places in the text as regularly accepted French words.

Laying Mains.—The *Sheffield Daily Telegraph*, which ought to know, says that the Derbyshire carters always take their half of the road out of the middle. We note the fact, and if we should go driving thereabouts shall know what to expect. Our contemporary, however, goes on to complain of the local electric lighting company for adopting a similar line of policy, and laying their mains under the middle of the footpaths instead of at the side, with the result that pedestrians are driven off the path into the roadway whenever there is any work being done to the mains. Possibly, however, the company have a good reason for what they are doing.

A Curious Discovery.—In the course of the excavations at Shoreditch in connection with the electric light installation one of the workmen struck his pick into an old well, and had, it is stated, a narrow escape of going to the bottom of it, and finding himself in 7ft. of water. The well is situated a few yards from the Standard Theatre, close to the end of Holywell House, and it is possible that this is the well that gave the name to the spot. If that is so, it was connected with the old Benedictine Priory. The antiquarians, however, will have no chance of discussing the point, as the Vestry, for whom the work is being done, decided to have the well filled in at once.

Labour Troubles.—The notorious strike at Thorneycroft's owing to the standing dispute between the unions representing the boilermakers and fitters is stated to be in a fair way to be terminated. Up to the present arbitration has not been very successful in the matter. On the other hand, it appears to be decided that there is to be a very big strike or lock-out on the Clyde, which will probably also affect the Belfast and Sunderland engineering firms. What has been published lately with reference to the state of things in the pressed glass trade, though of less immediate concern, should demand consideration from everybody who complains of what might be British trade going abroad.

Directory of Railway Officials.—We have received from the Directory Publishing Company, 8, Catherine-street, Strand, Mr. S. R. Blundstone's "Universal Directory of Railway Officials for 1896." This is the second year of issue of this directory, and besides the corrections necessary to bring it up to date, the present volume contains additional particulars relating to the Prussian and Russian State lines, and various railways in Sweden, Cuba, Spain, and the United States. A note in the preface states that the "contents have been compiled entirely from official sources," and therefore they ought to be as correct as is possible in the case of information which has to be collected from every quarter of the globe.

Motorcarts.—The show at the Imperial Institute having been closed, about a dozen of the motorcarts from there have been taken to Wembley Park, where at any rate there is more space for them to display their capabilities. Though the new Act has been passed it is not yet in force, as some people have found to their cost, and it has been complained of that there was great difficulty and trouble in getting motor vehicles down to Wembley, as the police refused to allow them to be driven there in the daytime. This seems eminently absurd, as nothing less than an immediate summoning of a special session of Parliament can prevent them running anywhere after November 15 next. Until then, however, the usual official opposition to anything that is new will have still to be reckoned with.

Nuremberg Exhibition.—An exhibition almost entirely devoted to the national interests of Bavaria has been open this summer at Nuremberg. The exhibition is in a park on the outskirts of the town, and access is gained to it by well-appointed tramways, particularly an electric line, on which the tramcars run at about eight miles an hour. The chief buildings are the industrial building and the machinery hall, but there are numerous pavilions

Digitized by Google

scattered about the grounds. The main machinery hall covers an area of 9,300 square metres, and there is only one line of shafting, driven direct by a steam-engine. The hall is crowded with machinery, and much of it is driven by electromotors, either directly or by belting, and besides this a great deal of the moving machinery in other buildings is driven electrically.

The Mining Engineers.—The Federated Institution of Mining Engineers, who have chosen Cardiff for their seventh annual general meeting, appear to intend to combine business with pleasure as much as possible. The meeting will open at noon on Tuesday, September 15, at the rooms of the South Wales Institute of Engineers, Park-place, when papers will be read. Then, on September 16, special arrangements have been made for visits to the Deep Navigation Colliery and the Great Western Collieries, and on September 17 to Symond's Yat, Tintern Abbey, and the Dowlais Steelworks. By the courtesy of the executive council of the Cardiff exhibition, members may obtain tickets admitting them to the exhibition for the week at 1s. each, and it is probable that on both Tuesday and Wednesday the whole of the members will dine in the large dining-room at the exhibition.

The Sussmann Lamp.—At the statutory meeting of the Süssmann Miners' Lamp Company, on Monday, there were quite a quantity of the company's lamps on view. They consist of a small 1-c.p. incandescent lamp, with a reflector placed inside a glass globe protected on three sides by a cover, and mounted on the top or lid of the battery box, the latter forming the stand. The connection to the terminals of the battery is by flexible leads and plug contacts. It is proposed to supply the lamps to the pitmen alight, and with the lids locked or sealed down, any arrangement for switching off being considered unnecessary, as the lamp will be in continuous use up to the end of the shift, when it is returned. Though provided with a hook of the usual pattern, the lamp may be placed on its side or upside down, and, according to the statement of the chairman of the company, will run for 12 hours, or on an emergency longer, but, of course, if its normal period is exceeded the power of the light falls off.

Budapest Exhibition.—The exhibition which has been held this summer at Budapest as part of the celebrations of the millennial anniversary of the kingdom of Hungary occupies a park to the north of the town, and is an affair of some very considerable magnitude. A narrow-gauge electric tramway on the overhead conductor system runs from end to end of the grounds, and access to the exhibition from the centre of the town is provided for by numerous tramways and by the electric underground railway. There are nearly 16,000 exhibitors and 160 separate buildings. The second largest building is the machinery hall, covering 12,000 square yards. The bulk of the machinery in it is agricultural, agriculture being the staple industry of the country. Messrs. Ganz and Co., of Budapest, have a building to themselves. Their most striking exhibit is a turbine intended to drive dynamos for power transmission up to 800 h.p. Around it are different sorts of electric motors and other machinery.

Telegraphic Interruptions.—In the official list published by the Berne *Journal Télégraphique* of August 25 the list of cable interruptions in which communications had not been restored by that date begins with the old Brest and St. Pierre cable dating from 1893, which might surely now be omitted. The others are the Puerto Plata and Martinique cable, which failed on December 19 last, and the African line beyond Mazoe, March 11. There then follow the Amazon Company's cable beyond Monte Alegre, May 4 ; the Cartagena and Barranquilla line in Colombia, July 4 ; the Salisbury and Umtali line to Beira, July 11 ; the Ecuador lines to Quito and other towns, August 11 ; the Radde and Khabarovka line in Siberia, August 19 ; the Pará and Maranham cable, August 6 ; and the Zanzibar and Mombassa cable, August 23. Communication with Bissao and Bolama was restored on August 5, after six days' interruption, and between Shanghai and Nagasaki after more than a week's cessation on August 2. There were short interruptions of the Saigon and Bangkok and of the Sheik Said and Hodeida lines. The Gibraltar and Tangiers cable, which failed on July 28, was restored on August 12, and besides two short interruptions on Siberian lines the only other noted is the failure of the Moulmein and Bangkok line between July 28 and August 7.

Undecided.—Matters seem very much at a deadlock in Glasgow with reference to the proposed adoption of electric traction for the tramways. At the usual fortnightly meeting of the Corporation Tramways Committee, the remit from the Town Council for further information regarding the question came up anew for consideration. Mr. Oatts proposed and Mr. Martin seconded that the papers lie on the table, and that the manager be instructed to get further information. Mr. King proposed and Bailie Thomson seconded that the matter be remitted to the Motor Committee for further consideration and to report. On a division, nine voted for the motion and nine for the amendment. The convener (which we believe is the Scottish equivalent for chairman) again declined to give his casting vote, so no conclusion was come to. The Council had really better decide the matter itself or enlarge the committee. The question of whether the committee want further information or not is not a very serious one anyway; too much knowledge is usually less dangerous and expensive than too little. Nor would one like to suggest that, as the committee find the balance of advantages so near that they are unable to decide one way or the other, they should toss up for it, and so get a decision one way or another. Such a course would as ill become the dignity of a committee of the second city in the United Kingdom as does their present attitude of irresolution.

Engineers in Manitoba.—Under the influence of the Canadian Society of Civil Engineers, the Manitoban Provincial Government has passed an Act which, among other provisions, contains the following: "On and after July 1, 1896, no person shall be entitled within this province to take or use the name and title of 'civil engineer,' or any abbreviation thereof, either alone or in combination with any other word or words, or any name, title, or description implying that he is a member of the said (Canadian) Society of Civil Engineers, or act as engineer in laying out, advising on, constructing or superintending the construction of any railway or public work, or any work upon which public money is expended, the cost of which shall exceed 500dol., unless such person is a member of the society hereby incorporated and registered as such under the provisions of this Act, or unless he is a duly qualified civil engineer, and entitled to use the title of civil engineer by virtue of some statute in force in this province, or by the authority of some institution of learning in this province having authority to confer degrees in civil engineering, or unless he has been practising as a civil engineer in this province at the time of the passing of this Act, or unless he is a member in good standing of some institution of civil engineers in Great Britain and Ireland, or of some national society of civil engineers of good standing in any foreign country." The provision in the last lines would seem to open the door to endless evasion,

Digitized by Google

Quite apart from the question of whether legislation of this character is desirable, we should have thought that any attempt to restrict the use of the letters C.E. in Canada was a matter for the Dominion rather than the provincial Governments.

Electric Stone-Crusher.—A stone-crusher driven by an electric motor, which has recently been installed at Peterboro in Canada by the Royal Electric Company, is described in the *Canadian Architect and Builder.* The crusher is used by Messrs. Corry and Laverdure, the contractors for the construction of the Trent Valley canal, to crush all stone required for that section of the canal, and the plant is said to be the first of the kind and the only one in commercial operation in Canada. The current to operate the stone-crusher is transmitted from the station of the Peterboro Light and Power Company, a mile distant. The motor plant consists of a 50-kilowatt alternating-current synchronous motor, with its exciter, and a 5-h.p. starting motor. The alternating current is taken by the motor directly from the transmission line at 1,000 volts. The stone-crusher is belted to one end of the shaft of the synchronous motor. To the other end are belted in tandem the exciter and starting motor, the attendant on the stone-crushing plant being informed as soon as the synchronous motor is in step with the alternator by a lamp going out in the usual manner. The plant was started in June, and it is stated that the crusher has been successfully doing its work every day since. It has been put to the utmost test; the greatest possible loads have been put on; the crusher has been jammed full of the hardest stones obtainable; the greatest variations possible in load, from nothing to the extreme capacity of the crusher, have taken place rapidly, but no variation in speed occurred, the synchronous motor meeting every demand upon it without change. Under these circumstances it is hardly surprising to find it added that Messrs. Corry and Laverdure express themselves as pleased with the operation of the plant.

The Junior Engineers.—At the summer meeting of the Institution of Junior Engineers the district visited was Edinburgh, Glasgow, and the Clyde. The programme, as already given in these columns, was duly carried out, and we last week noticed the visit of the members to Dumbarton. On the following day (Friday) various works were inspected at Glasgow and Govan, and in the evening the summer dinner of the institution was held at the Alexandra Hotel, Glasgow. After the usual loyal toasts, the president gave "The University of Glasgow,' which was responded to by Lord Kelvin, vice-president of the institution. To "The Institution of Engineers and Shipbuilders in Scotland," proposed by Mr. W. B. Clarke, Sir William Arrol replied. "Industrial Scotland," given by Mr. H. B. Vorley, was responded to by Mr. James Riley, and "The Institution of Junior Engineers," which was proposed by Provost Garvie, of Dumbarton, was acknowledged by Mr. H. J. Young. The concluding toasts were "The President," given by Mr. A. Anstruther Thomson, and "The Chairman and Vice-Chairman," proposed by Mr. W. E. Lilley. During the evening, in recognition of his efforts in promoting and carrying out the arrangements of the meeting, a presentation was made to the secretary, Mr. W. T. Dunn. On Saturday morning the Dawsholm Gasworks were visited, Mr. William Foulis receiving the party. Other members visited Messrs. Sir W. Arrol's works and the sewage precipitation works, which were opened to their inspection. The Glasgow electric light station was available for visiting in the evenings. Altogether the meeting passed off most successfully, and the occasion distinctly indicated the advantages which the younger members of the profession have the opportunity of enjoying under the auspices of this institution, the membership of which is now over 450.

Scientific Education.—The publication of Prof. Ostwald's views on this subject has produced a letter to the *Times* from a "Chemical Manufacturer," who says that there is a by no means small class of manufacturers in this country who have for years recognised the necessity of employing highly-trained chemists in their works, and this demand has, with few exceptions, to be met by recruiting talent from Germany or Switzerland. This is not done from choice, as foreign chemists will not accept posts in England unless they are much better paid than they would be in their own country, and they have a tendency to return to their native shores. As reasons for the lack of well-trained English chemists, it is suggested that the money available in this country for higher educational purposes (scientific) is spent in establishing and maintaining a large number of unsatisfactory technical schools, instead of a small number of good colleges. The individual schools are, consequently, often insufficiently equipped, and in most cases the professors are badly paid, the result being that some of the best men refuse to enter the teaching profession at all. Moreover, there is practically no State aid for higher education; whereas, in a German or Swiss university, students only pay one-third to one-half the actual cost of their education, the State providing the remainder. Finally, the whole system of higher scientific education in England seems to have been developed in the wrong direction for several decades. To establish technical schools in every borough of the kingdom may have its advantages, and is possibly an ideal system. But what we want above all is to develop a practical system first. Ask the average chemical manufacturer, be he Englishman, German, or Swiss, whether he is anxious his workmen, even his foremen, should know something about science. He will tell you that he wants workmen who carry out his instructions, and that the smattering of doubtful science his workmen may have acquired at the average technical school is worse than useless. What we must strive for is that an Englishman may have more opportunities of acquiring at home, at reasonable cost, as sound a higher scientific training as he can now obtain abroad. This will enable him to occupy with greater success the leading position as manager in a chemical or similar works, or to further by pure research work the particular industry in which he is engaged. To this end it seems of primary importance that the limited funds available for higher scientific education in the United Kingdom should be devoted to a relatively small number of the best colleges. This would be productive of better results than if such available funds are frittered away on a multitude of technical schools which, with the relatively small means at their disposal, cannot be equipped and managed otherwise than indifferently. Without altogether endorsing these views, it must be confessed that there is unfortunately a certain amount of truth in them, and the case might have been pressed still further if reference had been made to the deplorable waste of money on what passes for "technical" education with many country boroughs and county councils.

An American View.—Under the title of the "Era of Extravagance in the Electrical Business," Mr. Burton E. Greene has contributed an article to the New York *Engineering Magazine*, the general drift of which is to show that, though the electrical business in America has been somewhat unsatisfactory in the past, now, "after 16 years of expensive and misguided struggle, of fever and unrest,

Digitized by Google

the business has touched rock bottom, and can take its place among the stable and substantial industries of the country." Mr. Greene does not think much of the prospects of the new lamps that Mr. Macfarlane Moore, Mr. Edison, and Mr. Nikola Tesla have invented or are going to invent. In fact, Mr. Tesla says he would hold gas or electric lighting stock, if he had any, for at least a year or two longer. In spite of this declaration that he is not going to upset the electrical world for the next 24 months, we are inclined to think that of the three men Mr. Tesla is on the whole the likeliest to produce something practical. Mr. Greene does not seem to approve of research work from the money-making point of view. That we can very well understand—it so very much depends on the qualifications of the experimenter. In reference to what follows, it must be remembered that a "silver" policy has a direct as well an indirect effect on all work carried on subject to a statutory maximum charge, for instance, in the case of an electric tramway "franchise" with fixed fares. Mr. Greene's final conclusions, then, are as follows: "Expenses for experimental work have not been entirely eliminated. They never can or ought to be eliminated from any progressive trade depending upon invention for supremacy. But they have been reduced to less than one-tenth of the average 10 years ago. Extravagant salaries are no longer common. They have been very generally adjusted to meet changed conditions. There is no longer a scarcity of men with a knowledge of electrics. In fact, the market is becoming overcrowded. All along the line sensible economies have been put into practice, and the expenses of doing business are nearly as low as in any of the old-established industries. District managers and district offices, which were in reality so many distinct business establishments where extravagance reigned supreme, have been abolished, without any great diminution in sales. Comparing the present situation with any other period since 1880, there is nothing but encouragement for those engaged in electrical manufacture. They are offering for sale what the public must buy. The demand is as certain as the demand for ploughs or farm wagons. The boom period has passed for ever. The industry will no longer suffer from so many diseases peculiar to itself. It will thrive as general business thrives, and be less susceptible, perhaps, to a general depression than almost any other. The chief danger to-day is that which threatens alike every commercial enterprise in America, from the railroads to the farmer, even to the individual labourer — the danger of an unsettled financial policy. Of the ultimate triumph of the gold standard there can be no question. Meantime, the evidence of financial heresy spreading through large sections of our country cannot be ignored. With this question finally settled the profitableness of the electrical trade would be beyond question."

Light Units.—The Geneva Electrical Congress has resolved on a system of photometric units, and it only remains to get all the rest of the world to use them. The units are the French units, and were pretty strongly criticised by the Germans and only weakly supported by the Italians, so that, England and America being unrepresented in the discussion, it can hardly be said that the system is at present certain of adoption by all the principal civilised nations. The matter came up on a report on the subject by Prof. André Blondel, who, however, was unab'e to be present. The units are not numerous, so that the Latin and Greek dictionaries will supply designations enough without taking random dips into a bag containing all the names of eminent discoverers and experts in the art of lighting from Prometheus downwards. These worthies therefore still remain in obscurity among the other shades, and Prof. Ferraris had no need to fight them with a phantom archimedes and torricelli, as he did in the case of the magnetic units. Nevertheless, the "pyr" was judged too recondite for the multitude, and the "bougie decimale" was adopted, a quantity named apparently on the *lucus a non lucendo* principle, because it is somewhere about one-twentieth instead of one-tenth of the Violle standard. However, it must be admitted that it would be a dull fire or a very small one that only gave one pyr. The new quantities have Roman and Greek capital letters assigned to them which clash with those already in use in electricity. The new units are [I], for intensity (the German expression "strength of light" is better), the bougie decimale, and for [Φ], the flux of light, the lumen. For [E], illumination, the lumen per square metre. This quantity will be a decimal in most cases of outdoor lighting—in measuring moonshine, for example—though it ought to have a fair amount of digits in the daytime. The name of this unit is the lux. The other two units have at present no special names: they are for [*e*], brightness, the bougie per square metre and [Q], quantity of light, the lumen-hour. Exception was taken to the unit of brightness, but when you have to measure anything between the brightness of a glow worm and a glow lamp you must have several digits somewhere. So far, then, there was no great trouble; it was about the standard that the disputes occurred. The report preferred the Hefner amyl acetate lamp to the Vernon Harcourt pentane one. The American standard of incandescing carbon at a given temperature was not practical, and the Violle standard of melting platinum was recommended as the theoretical one. All the Germans objected to this on the reasonable ground that it was absurd to gauge a fair instrument like the Hefner lamp by an utterly uncertain standard, Dr. Köpsel saying that at the Reichsanstalt, using either the oxy-hydrogen flame or the electric current for fusion, they were unable to get the platinum standard certain within 25 per cent. It was ultimately determined, however, by a majority that the report should be adopted, and the bougie should be represented "provisionally" only and for industrial requirements by the Hefner lamp. It may be suggested that as the lights in ordinary use are of different colours, and it is certain that the relative intensities of light of different wave-lengths is not by any means the same for all persons, it will be necessary before a system of photometric units can attain theoretical perfection to define a standard eye.

Electrical Congress at Geneva.—The International Electrical Congress at Geneva mustered about 250 members, but, as was expected, it was not quite so international as it might have been. Among the members the French and Italians appeared to predominate, but so far as the papers and discussions were concerned the German influence was strong. Our Institution of Electrical Engineers sent no delegates, and though Prof. Bradley came from the American Institute of Electrical Engineers, it may be said that the English-speaking countries and their work were practically unrepresented. We published in advance the programme of the subjects discussed. The decision of the congress on the question of photometric standards forms the subject of another note, and though we may possibly refer at a future date to some of the papers read, at present a very brief notice of the proceedings will be sufficient. They began in German with a report by Dr. Wietlisbach, of Berne, on the disturbances in telephone lines produced by strong currents, and were continued by Dr. Palaz in French. The report cannot be summarised very briefly, but there was little

Digitized by Google

novel in its recommendations. Prof. Hospitalier introduced the subject of magnetic units, and proposed the adoption of the system of units settled by the American Institute of Electrical Engineers in 1894, including their application of the names Gauss, Weber, Gilbert, and Oersted. Pros. Ferraris objected, and started off a burlesque system of units of pressure and density entirely of his own composition. Mr. Gisbert Kapp found no difficulty in dealing with millions so long as they were only millions of lines of force (or units of brightness), and so on with the others—in fact, Prof. Kovalevski was about the only man who backed up the proposition. Ultimately, in order to avoid a direct negative, on the motion of Prof. Mengarini, of Rome, the congress suspended the debate without any resolution being passed. Consequently, so far as the congress is concerned, it is open to everyone to go on discussing $4\ \pi/10$, and the rest of it. It looks as though the Fates intended to deny to Weber the immortalisation of his name as a unit after all. Perhaps the system will be more lucky that leaves it out. On the subject of power transmission there was a paper by Mr. André Blondel, which dealt with wattless currents. Most of the known remedies and palliatives for these were referred to, and the conclusion arrived at was that further research was required on the subject. The discussion went off into mere questions of nomenclature, the name "wattless" being apparently more objectionable to the professors than the actual current. Prof. Ferraris would have none of it in Italian. The French speakers were divided on the subject. If a foreigner may express an opinion after, such un-French-looking words as *self-induction* and *spring-jack*, *dewatté* may very well pass. The expression was made in Germany, like many other things, and adopted in England, because it could be brought over straight away without trouble and was found useful. It is a pity that it has not proved possible to do the same with *drehstrom*. The congress then got back to business, and Mr. René Thury showed that there was a good deal to be said for the use of high tension continuous instead of alternating currents for power transmission. In one way or another this last subject occupied the rest of the time of the congress. There was nothing strikingly novel, but the matter may possibly be recurred to in a future note. Prof. Raoul Pictet's lecture on low temperatures and cathode rays was somewhat disappointing considering the eminence of the author.

The British Association.—The meeting of the British Association on the 23rd inst. at Liverpool will be a revisit to that city after an interval of 26 years. The local secretaries, Prof. Herdman and his colleagues, Mr. Isaac C. Thompson and Mr. W. E. Willink, have been working hard to make the meeting a success, and the preparations are now practically complete. The reception-room and general offices will be at St. George's Hall in the centre of the city, a few yards from Lime-street Station. St. George's Hall has just been redecorated and provided with electric light. The Geography Section will occupy the concert-room of the hall, and three other sections (Geology, Anthropology, and Mechanical Science) have been given rooms in the adjoining Public Museum and Walker Art Gallery. The section of Economics will be at the Town Hall, while the remaining sections—Physics, Chemistry, Zoology, Physiology, and Botany—will be in the laboratories and lecture theatres of University College, over half a mile from the reception-room. A tramway route, however, leads from the reception-room to the corner of the college, and arrangements will be made for omnibuses in addition to the tramcars. The Philharmonic Hall has been engaged for the president's address and the two evening discourses by Dr. Elgar and Prof. Flinders Petrie. Prof. Fleming's lecture to the working classes will be given in the Picton Lecture Hall. The first conversazione, given by the Earl of Derby, as Lord Mayor of Liverpool, will be held in the Town Hall, and the second, that arranged by the local committee, will be in the Museum and Walker Art Gallery. The large amount of space available will enable short lectures, demonstrations, and exhibitions to be a prominent and attractive feature of this conversazione. The subject of the presidential address by Sir Joseph Lister has been somewhat jealously guarded, but it may reasonably be expected to deal with the biological rather than the physical side of science. The president of Section A, Mathematical and Physical Science, is Prof. J. J. Thomson, F.R.S., of Cambridge, who in his address will deal with the teaching of physics, Röntgen rays, the passage of electricity through gases, and the movement of the ether. In Section G, Mechanical Science, Prof. Douglas Fox will deal in his address with the advances in mechanical science and engineering, especially in connection with Liverpool, during the last 25 years. In this section Prof. Mengarini has promised to give some account of the electric light and tramway systems of Rome. Mr. E. W. Anderson will have some notes on electric cranes, and Mr. W. A. Preece will speak of a test for incandescent lamps. Mr. W. W. Beaumont will discuss "Why railway rails break." Prof. Hele Shaw will deal with engineering laboratory apparatus, and his paper will be followed by a reception and demonstration in the Wallace Engineering Laboratory. Motorcarts will be dealt with by Mr. A. R. Sennett, and it is expected that a number of horseless carriages will be shown in operation. Three important reports will be presented to this section—the report of the Committee on Tides, the report of the Committee on Small Screw Gauges, and the report of the Committee on the Standardising of Instruments in Engineering Laboratories. Dr. Ludwig Mond, F.R.S., will preside over Section B, Chemistry, and in his address will deal with the history of the manufacture of chlorine and the influence of the progress of pure science upon its development. In this section Prof. Ramsay will read a paper on helium, and there will be a number of other communications on helium and argon. Prof. Norman Lockyer will read a paper on "The Synthesis of the Elements," a title which, so far as we know, is still somewhat premature, and it is expected this will lead to a discussion, in which Mr. Crookes and others will take part. There are interesting papers to be read in the other sections, but these, of course, are on subjects of less immediate concern to most of our readers. The metric system comes up in the Economics Section. Pithecanthropus, which the general public will insist on miscalling the "missing link," will come up under anthropology, while Dr. Gaskell, in the new section of physiology, will bring out a new theory as to the origin of the vertebrates. He is going to explain quite a quantity of rudiments that have puzzled biologists, but it may be safely said that those competent to understand and criticise his hypothesis will be few and select. The Geographical Section is, of course, the region of "lions," but it is understood that the attempts to capture Dr. Nansen for it have failed. Finally, it may be said that the Publications Sub-Committee have drawn up two books, which will be presented to members; the first is a scientific handbook to Liverpool and the neighbourhood, containing articles on the history and antiquities, the geology, the entomology, marine biology, botany, the vertebrate fauna, climate, river, and tides, docks, and other engineering works, trade and commerce, and the chemical industries. The second book is a complete guide to the various excursions.

Digitized by Google

SOUTH SHIELDS ELECTRICITY WORKS.

The Municipality of South Shields has always regarded electricity with a favourable mind, and the ratepayers will now begin to reap the advantages which an enterprising foresight on the part of their representatives in past years made possible. Up till the last few years, the question as to whether it was advisable for cities and towns to take up the position of suppliers of electricity, or whether it was advisable to let private companies start the undertaking, was a question which considerably exercised the minds of the elect of the ratepayers; but among the corporations who wisely decided upon what was then the bolder policy was that of South Shields. Having decided to have an electricity supply is one thing, and having obtained it is quite another. The South Shields electric lighting provisional order is dated 1891: the inauguration of it has now to be dated 1896. The history of the movement is brief and unsensational, but it illustrates well much of our civic life of to-day—the quiet, steady plodding away at detail after detail until a successful result is reached. In 1893, the matter may be said to have been fairly started. In that year the Corporation obtained a report from a gentleman living in the neighbourhood, and on that report, a committee was appointed—the Electric Lighting Committee. A consulting engineer was not engaged, inasmuch as the committee contained two well-known Tyneside engineers of great experience—Alderman Rennoldson and Alderman Eltringham. North-countrymen are nothing if not practical and 'cute, and their idea of a consulting engineer was a man who might be of a very scientific turn of mind, with an overwhelming desire to conduct interesting experiments at the expense of the Corporation. Wherefore they advertised straight away for an electrical engineer who would design a system and draw up all specifications. The result of that advertisement was that Mr. Joseph A. Jeckell, A.I.E.E., was appointed borough electrical engineer in November, 1893, and he has achieved success, not only as an electrical engineer, but as a man who is able to specify what is really wanted and to see that he gets it. Such work can only be the result of experience, and Mr. Jeckell gained a great deal of his experience in two very good schools—London and Manchester. Having appointed an engineer, the committee set about finding a site. They first of all rather fancied one in the centre of the borough which was available at the time, but after matured deliberations this was discarded. Then they heard of the present site, which was called Black's Old Foundry, West Holborn, and eventually succeeded in purchasing it at a cost, including legal expenses, of £4,600. The site is an admirable one. It is situated on the river's edge, and is also to all intents and purposes as near the centre of the borough as it is possible to be. When one considers that South Shields has a population bordering on 90,000, it will be understood that this fact is of considerable importance. The area of the site is about 2,000 square feet, and there is a good river frontage. There is room for extensions large enough to accommodate all the plant that South Shields is ever likely to require. The whole of the plans and specifications were got out by Mr. Jeckell, but it was not till February, 1895, that the contracts were let, and then the Board of Trade and the Local Government Board had to be dealt with, so the work of laying cables, clearing the site, and rebuilding was not commenced till June, 1895. Permission to borrow £28,000 had previously been obtained.

Now the works are finished (until such time as extensions are necessary) and the plant is laid down, and, with the exception of a few details, everything is very shipshape and satisfactory. The buildings, which are from Mr. Jeckell's designs, have no pretensions to great architectural beauty, but they look as if they mean what they do mean—business. They are chiefly of red brick, solid and capacious. Utility was evidently the key to Mr. Jeckell's design. Not an inch of space is wasted, as every part is adapted to the machinery to be housed. That is the secret of successful designing. The buildings were erected by Messrs. W. and R. Brown at a cost of £3,124. 15s., and the estimate got out by Mr. Jeckell was for £3,100, which is something to be proud of. Mr. Fred. Rennoldson, of South Shields, was clerk of the works, and he got out the bills of quantities in the first instance.

The Market Place, South Shields.

The system of supply adopted is the high-tension alternating one, with automatic transformers buried in the street. These supply low-tension mains in the busy parts of the town, but in some scattered residential districts transformers will be provided for each consumer. The area covered can be seen in Fig. 1, which also shows the position of the supply station relatively to the area in which mains are now laid. The sides of the streets along which low-tensions mains are laid have been shaded in the plan. As will be seen from this, there are four transformer stations at present in the district, and the high-tension mains embraces a much larger area than the low-tension. It was originally intended to complete high-tension ring through Claypath-lane, but now these mains are carried further out, as shown, so that a good residential district can be tapped.

Steam Generating Plant.

The contract for this part of the work and including the necessary steam-pipes, etc., was placed with the noted firm of Black, Hawthorne, and Co., of Gateshead. The two

Digitized by Google

boilers are of the marine type. By the courtesy of the above firm we are able to give the fully detailed elevations, Figs. 2 and 3, which show every leading dimension. These boilers are each guaranteed to evaporate 5,000lb. of water per hour at a pressure of 160lb. The following are the areas of the heating surfaces of these boilers: the furnaces and combustion chambers, 197·34 square feet; the back tube plates, 23·54 square feet; the front tube plates, 16·12 square feet; 118 3½in. outside diameter tubes, 743·00 square feet; total heating surface, 980·00 square feet. All the plates, rivets, and stays in these boilers are of steel. The tubes are wrought iron, and are attached to the tube plates in the manner shown in Fig. 3. All the rivet holes were drilled, and those in the shell were drilled after the plates had been bent. The working pressure of these boilers is 160lb. per

Feed-Pumps.—These were included in the contract given to Messrs. Henry Watson and Sons, of the High Bridge Works, Newcastle-on-Tyne. There are two feed-pumps for the boilers, of the duplex double-acting type, each capable of feeding both boilers simultaneously. The pumps have 4½in. diameter steam-cylinders, 3in. pump-chambers, and work with a 6in. stroke. They are arranged side by side, and draw their feed supply from a cast-iron hot-well, of ample capacity, placed near. They exhaust into the same hot-well, which was also constructed by Messrs. Watson and Sons. These pumps and their connections are well arranged in the boiler-house, and work smoothly and well. The above-named firm have also supplied a compact and well-arranged plant of condenser circulating pumps, and auxiliary air-pump and condenser, etc.

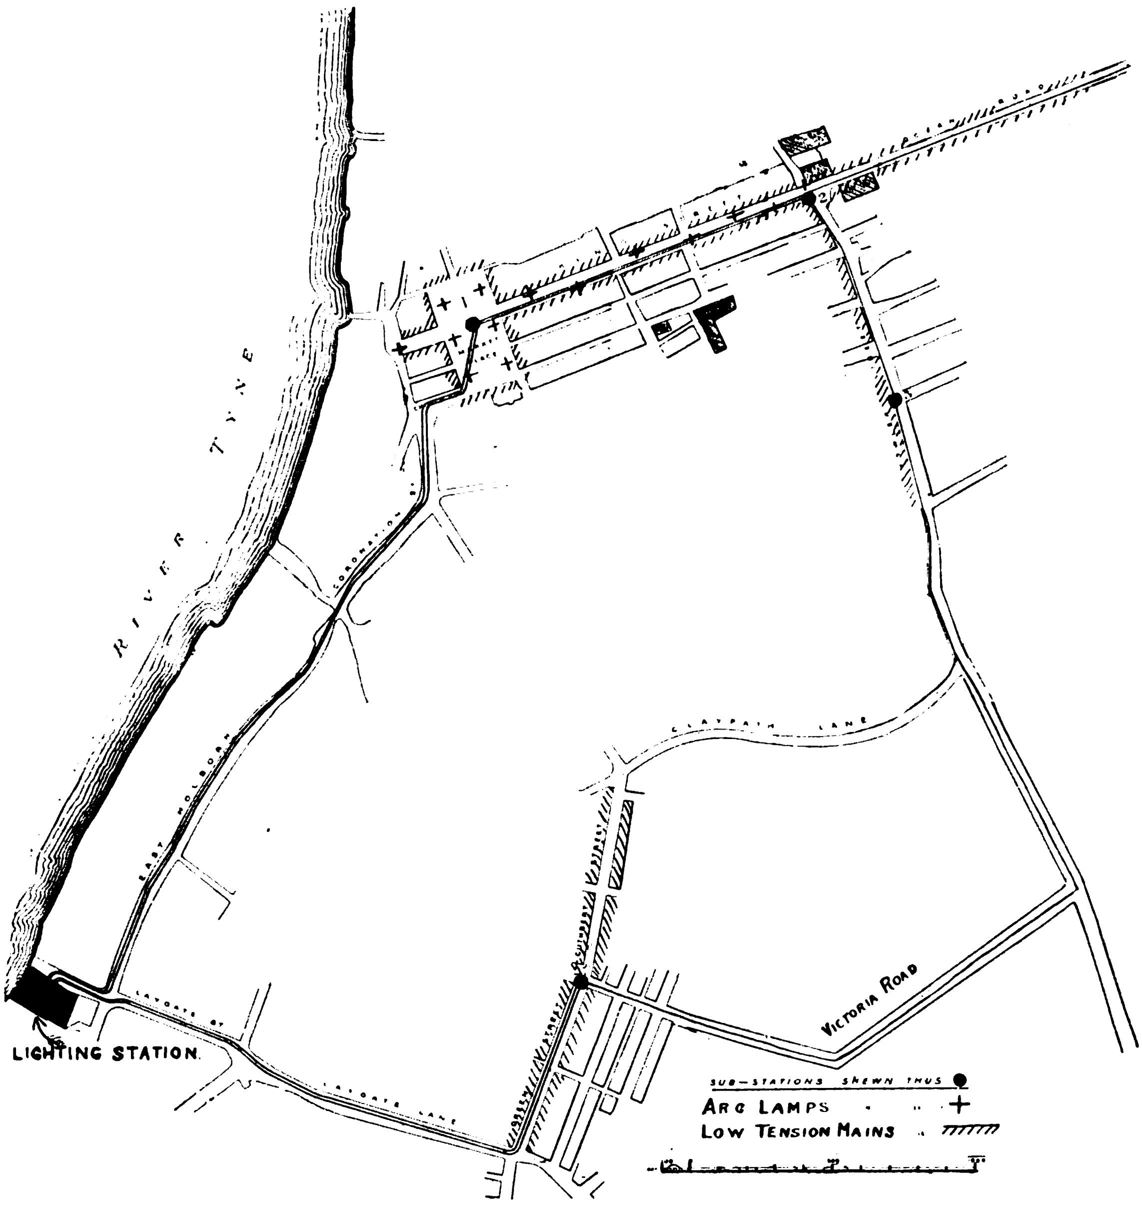

FIG. 1.—Plan of Streets in South Shields, showing High-Tension Mains.

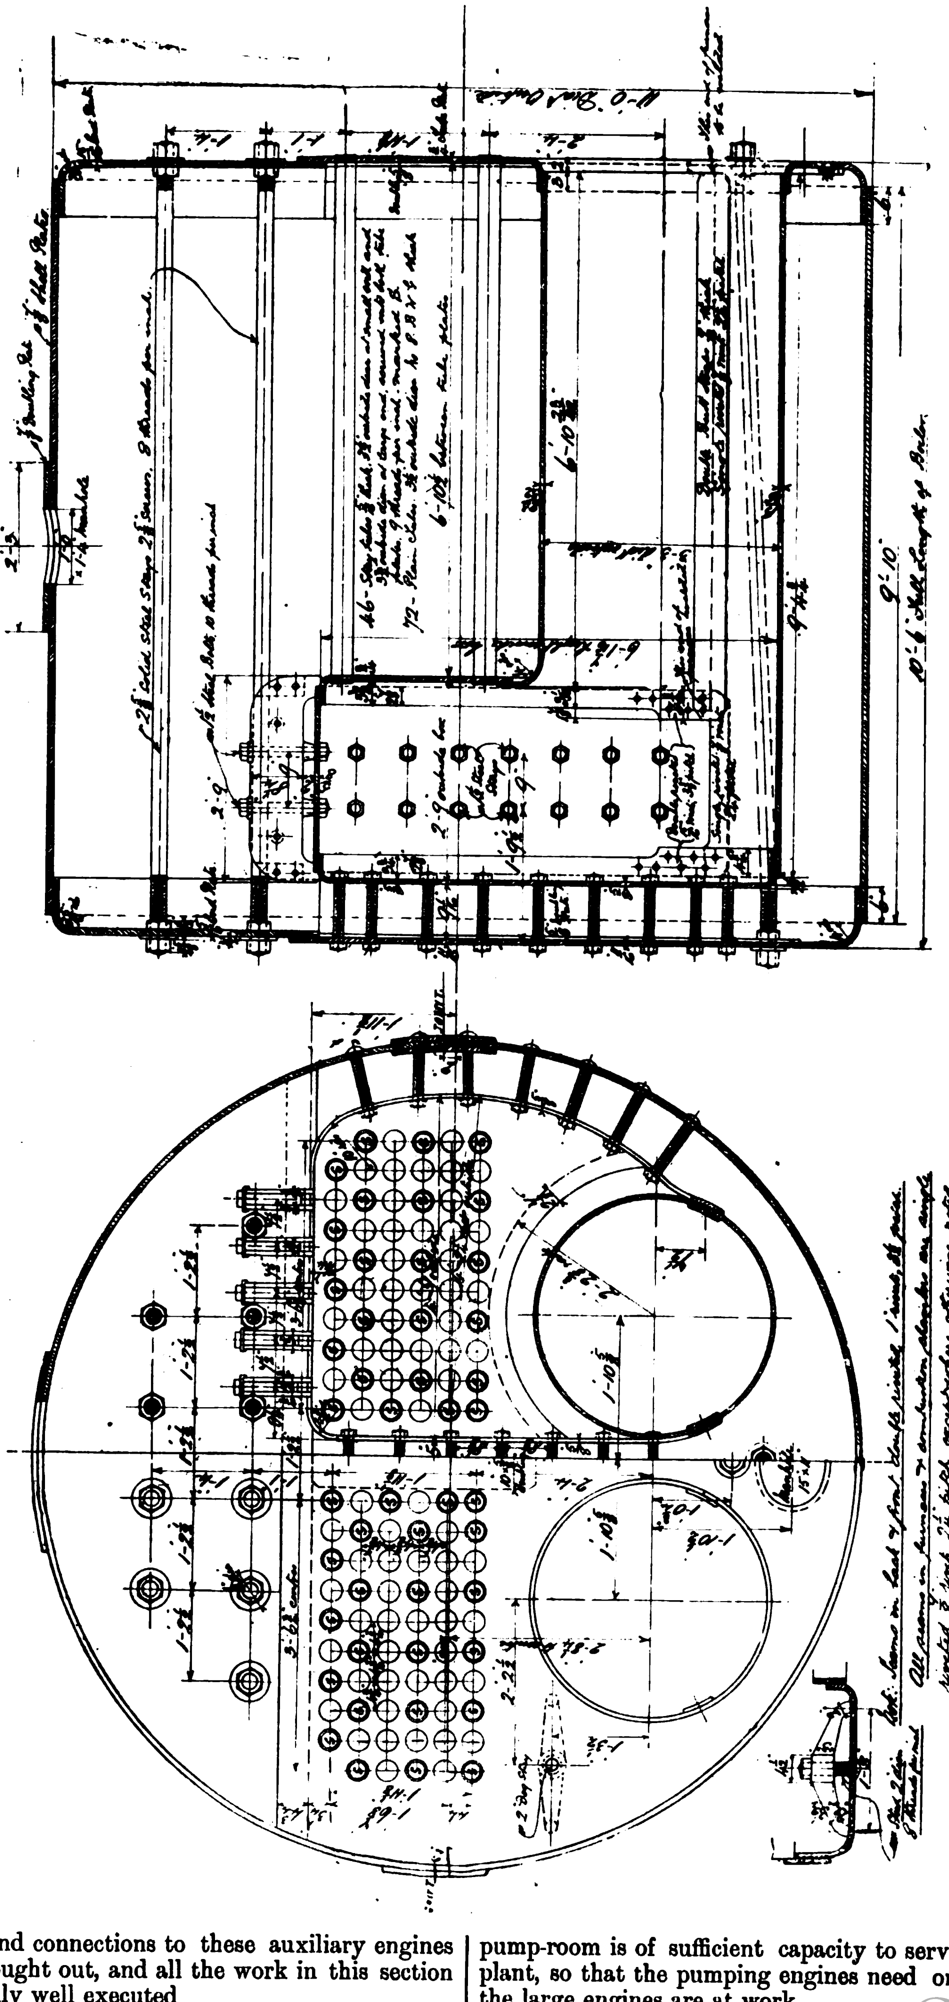
square inch, but they were tested up to 320lb. per square inch after being placed in their seatings. They were built under the inspection of Lloyds, to Mr. Jeckell's specification, and have been certified by them after final examination. The makers have also guaranteed that these boilers shall evaporate 10lb. of water from and at 212deg. F. per pound of good Northumberland coal burned in the furnace when steaming at the guaranteed rate of 5,000lb. of water per hour. Fig. 4 shows details of the riveting of a horizontal joint in the rings, and the following details are of interest in connection with this illustration: The inside butt straps are ¾in. thick, and the outside butt straps ⅞in. thick. Also, taking the strength of the solid plate as 100, the strength of the plate between the holes then is 87·13, the strength of the rivets 93·93, and the strength of the plate on the 4¼in. pitch line 93·04.

Duplex Circulating Engines.—Adjoining the main engine-room is the pump-room, in which are placed the two large direct-acting duplex pumping engines. Each pump has 7½in. diameter steam-cylinders, 10in. pump-chambers, and works with a 12in. stroke. Each is capable, when supplied with steam of 160lb. per square inch and running at normal speed, of delivering 16,000 gallons per hour into a large cast-iron tank (constructed and erected by Messrs. Watson) overhead. This tank practically forms the roof of the pump-room, and from it the water flows to the jet-condensers by gravitation. From the illustration (Fig. 5) it will be noticed that these circulating engines are of neat design, and that the valves and steam-chest are all accessible from the front. The engines work evenly, and without any of the kick or jar sometimes found in pumping engines of this type. The auxiliary air-pump is placed

Digitized by Google

in the main engine-room, and carries a small condenser. It works in connection with one of the main engines. The system of pipes and connections to these auxiliary engines has been well thought out, and all the work in this section seems to be equally well executed



FIGS. 2 AND 3.—Sections and End Elevation of the Boilers Used at South Shields.

In designing this part of the plant the engineer has thought of labour economy. Thus, the tank above the pump-room is of sufficient capacity to serve the light-load plant, so that the pumping engines need only be run when the large engines are at work.

Digitized by Google

ENGINE-HOUSE PLANT.

The whole of the generating machinery and the switchboards were included in Messrs. Ferranti's contracts. The engines were supplied under a sub-contract by Messrs. J. and H. McLaren, of the Midland Engine Works, Leeds. In specifying his requirements for the engines we understand that Mr. Jeckell recognised the importance of economy at light loads. In consequence, great attention has been paid by the makers to this point. In all, three engines have been supplied—one for day load, and two larger ones for taking the main load. The larger engines are triple-expansion and of the surface-condensing inverted cylinder type, similar to the three supplied to Oxford in 1892, which have been so successful in giving economical results. The makers are justly proud of the repeat orders they have received in consequence. The two engines at South Shields are used to drive 100-kilowatt alternators; have cylinders respectively 9⅛in., 14¼in., and 22½in. diameter, and the stroke is 24in. The crankshaft, which is a three-throw, is coupled direct to the axle of the alternator by means of a flanged coupling solid with the shaft. The distribution of steam is controlled by McLaren's patent automatic expansion governor, acting on balanced valves, in which the friction is almost entirely done away with. By means of this governor the speed can be controlled to within 2 per cent. up or down, notwithstanding any variation

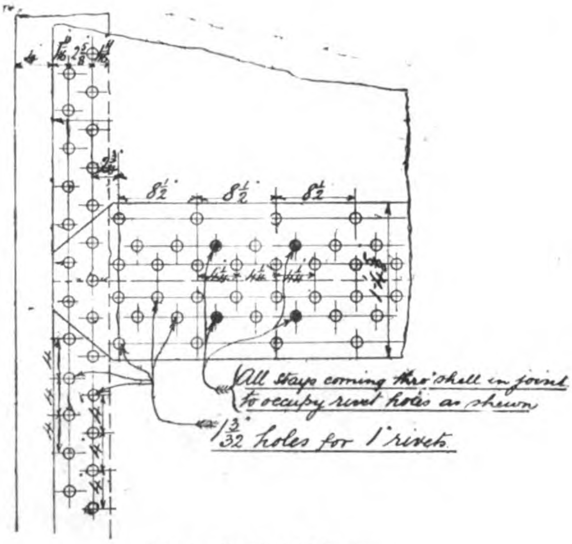


FIG. 4.—Details of Riveting.

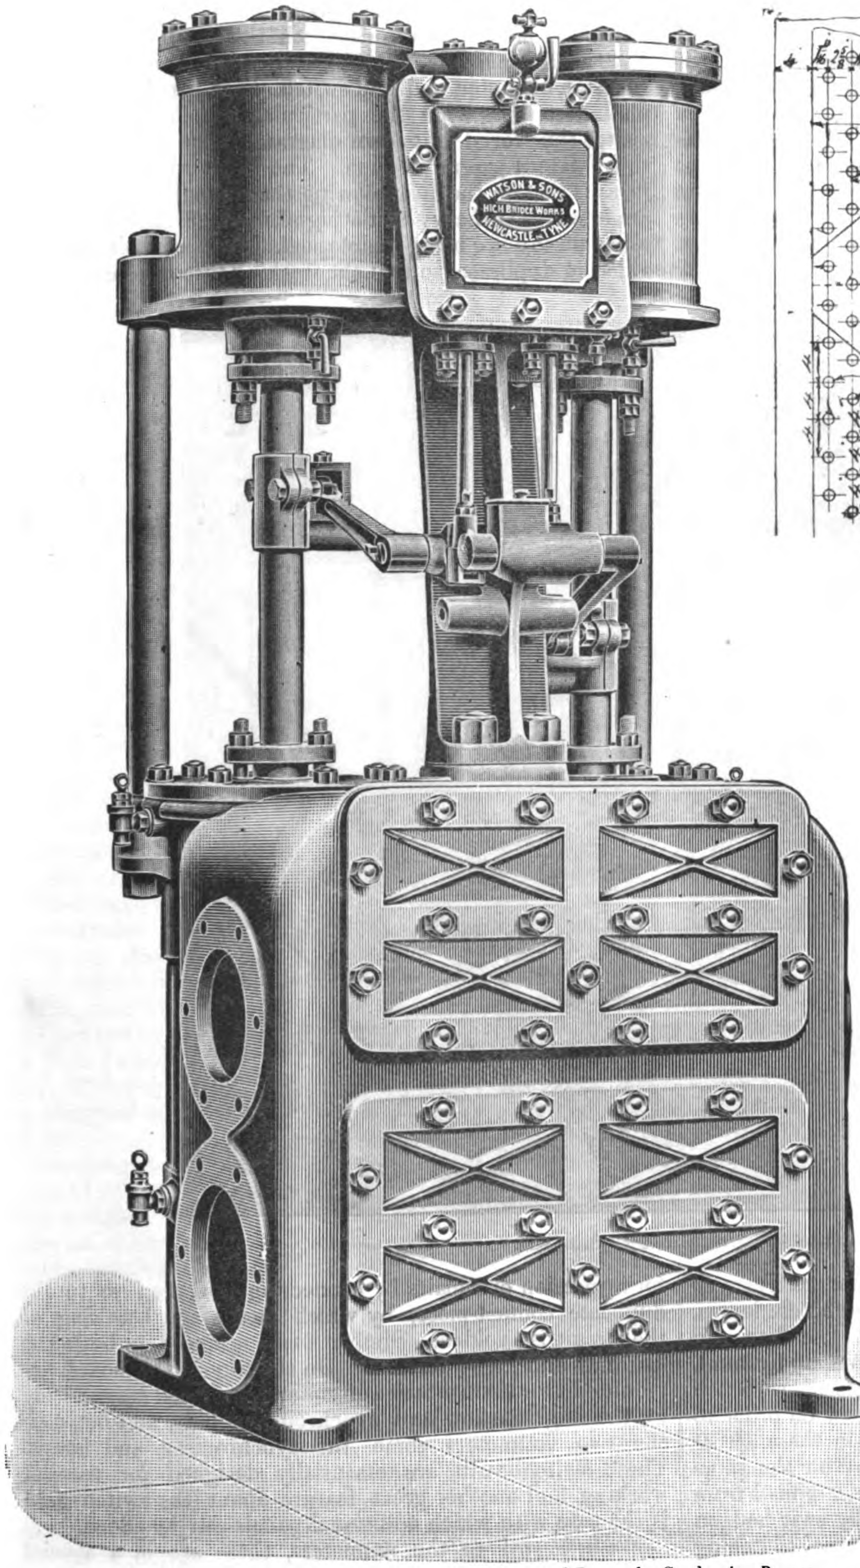

FIG. 5.—View of the Duplex Direct-Acting Engines and Pumps for Condensing Purposes.

in the load. The speed of the engine can also be increased or decreased from 5 to 10 per cent. above or below the normal by means of a simple speeding gear, whereby the number of revolutions can be varied while the engine is running, to suit the requirements of the moment. Parallel running can thus be easily secured, as the three-throw cranks, giving six impulses per revolution, give a far steadier turning moment than can be obtained from any single or double crank engines. All the cylinders and covers are properly jacketed and efficiently drained. These engines were tested at the engineer's works by Mr. Wilson Hartnell, of Leeds, and Mr. J. A. Jeckell previous to being delivered, and the following good results were obtained: the mechanical efficiency of the engines was found to be 94·2 per cent.; the steam consumption was only 13·1lb. of water per indicated horse-power per hour, including the waste from the jackets, which was weighed against the engines. This consumption represents the mean of three equal periods of running at half, three-quarter, and full load respectively. The high efficiency is no doubt largely due to the excellent vacuum (28lb.) which was continuously maintained in the condenser. The small engine for driving the 15-kilowatt day-load alternator and the exciter is of the ordinary compound inverted high-speed type made by the firm; it runs at 300 revolutions per minute.

Alternators.—These are of Messrs. Ferranti's flywheel type, and are similar to those installed at Southport, Islington, and Portsmouth. The field-magnet system is built up on the rim of the flywheel, radial poles being inlet

Digitized by Google

into the rim. The exciting coils consist of bare copper strip wound in a spiral, with insulation between adjacent turns. The armature is arranged outside the flywheel, and consists of a laminated core with windings sunk in the iron. A good mechanical construction is thus obtained, which is likely to give little trouble. The output of each of these alternators is 100 kilowatts. The voltage at the terminals is about 2,000, and the frequency is fixed at 50 complete cycles per second. This will allow of Continental makes of motors being used at reasonable speeds. Each large alternator is also provided with an exciter on the same shaft, but spare exciting gear is available as follows: The day-load engine is coupled direct to a small 15-kilowatt alternator on one side, and on the other to a direct-current 10-kilowatt dynamo. This latter machine will normally be used only as a day-load exciter, but its output is sufficient to excite both of the larger alternators at the same time. Arrangements are made at the switchboard for rapidly putting this dynamo on to the exciting circuit in case of need.

into the wall of the station, there being no back connections of any kind. The switch gear installed at present is sufficiently large to control four dynamos, two incandescent circuits, and two arc light circuits. Simplicity is a great feature of the switch gear, as the main supports have vertical sliding division pieces fixed into them, and the division between each upright slate is all the space required for the switch gear necessary to control either an alternator or a circuit, there being first the ammeter, underneath this comes the high-tension single-pole switch for breaking the 2,000-volt circuit, and underneath this switch on another slate shelf comes the oil fuse, and below this the exciter rheostat, ammeter, and field switch. Each panel bears a name plate describing what the particular switch controls, each switch thus forming its own diagram. The fuses in use are the Ferranti patent oil type. The great point about these fuses is that on the fuse blowing the contacts carrying same are immersed in heavy insulating oil, thus preventing the possibility of any arc being maintained. Fuse contacts are provided in duplicate, so that the working fuse can be removed

FIG. 6.—Ferranti Standard Switchboard.

Two rectifiers have also been supplied by Messrs. Ferranti and Co. These are each capable of feeding 30 arc lamps, and as only 14 arc lamps are at present in use they will have an easy time for a few months. We understand, however, that the Corporation are so pleased with the market lighting that additional lamps are now on order to be used in other streets. A new feature in these street lamps is that of having incandescent lamps on the same lamp-post for use after midnight. These are supplied from the low-tension mains, but are automatically switched on when the rectifiers are cut off at night. The usual switching gear for interchange of circuits and for reversing the polarity have been provided. A full account of a similar plant at Tunbridge Wells will be found on page 392 of our sixteenth volume.

SWITCH GEAR.

The switch gear at the South Shields electricity works installed by Messrs. Ferranti is constructed according to their standard methods. No wood or other inflammable material is used in its construction. The main supports which carry the switches, ammeters, etc., consist of black enamelled slate 2in. thick. These supports are built direct

for inspection or repairs by connecting a spare fuse to the duplicate contact-piece, by which means the breaking of the circuit is avoided. Similar fuses are used on both the dynamo and cable circuits. On the top of the board are mounted two electrostatic voltmeters, connected respectively to the high-tension and synchronising bars, and between the two voltmeters come the synchroniser and lamps. These switchboards are essentially designed for parallel working, and another great feature about the switch gear is the ease with which additional panels can be added.

With regard to the ammeters, these are of a special kind, and have been brought out by Messrs. Ferranti in order to meet a demand for an ammeter which could be read with ease and accuracy at a distance. As will be seen, the scale is vertical, and a large pointer is used to indicate the current. The divisions are wide compared with other ammeters now on the market. The very fact of the scales being vertical renders them much easier to read than ammeters with a semi-circular scale, quite apart from the fact of the wider divisions obtained between the indicating figures.

Messrs. Ferranti and Co. have devoted great attention

Digitized by Google

to the design of their switching gear. Fig. 6 shows the Sheffield combination, which in detail resembles the one at South Shields, but is approximately twice as large. The individual panels for controlling feeders and machines are all uniform in design, occupying exactly 6in. horizontally. The compactness of the design is due in a great measure to the use of single-pole switches and fuses. The other poles of the alternators are permanently connected to the outside conductors of the concentric cables and are earthed. With large boards, as with the one illustrated above, the machines and feeders can be grouped into two sets at full load. This grouping minimises the effects of a sudden fault, and is preferable, when a large output is concerned, to running the whole of the machines on to one pair of 'bus bars. Thus in the switching gear erected by this firm for the City of London Company the load can be sub-divided into four main groups at full load, and again united into one group at light load.

(To be continued.)

SOME ELECTRICAL FEATURES OF THE UNITED STATES BATTLESHIP "INDIANA."*

Of the several heavy-armoured battleships of the United States Navy the "Indiana" is the most formidable, and in her design and equipment presents to the electrical as well as naval engineer the greatest interest. This ship was placed in commission on November 20, 1895. She is 348ft. long, 69ft. 3in. in breadth, has a draught of 24ft., and a displacement of 10,288 tons. She is provided with twin screws, each operated by triple-expansion engines, and which are capable of driving her at a speed of 16 knots per hour.

The main battery of breech-loading rifles consists of four 13in., carried in two turrets, one forward and the other aft, eight 8in. mounted within four turrets situated at the four quarters of the ship, and four 6in. Each discharge of the 13in. rifles produces a reacting pressure at the breach of 2¼ tons per square inch and a recoil of about 4ft. The secondary battery consists of 20 six-pounder and six one-pounder rapid-fire guns and four Gatlings. The thickness of the armour is 18in. and is of Harveyised nickel-steel. Thirty-six officers and 434 men constitute the crew, the commander being Robley D. Evans.

This magnificent specimen of naval architecture was built for the United States Navy, at a cost of £604,000, by the Wm. Cramp and Sons Ship and Engine Building Company, Philadelphia. Of greater interest to the reader is the electrical equipment which constitutes the basis for this article.

Mounting to the bridge on the mast, we find there installed two 24in. projectors or searchlights, one on the starboard, the other on the port side, each being furnished with an electrical control-stand, consisting of two small motors, one permitting of lateral training, the other of vertical. These motors are operated from a small platform above the bridge. The lights are rated at 20,000 c.p., and have horizontal carbons placed perpendicular to the Mangen or parabolic reflector, according to which is each is provided. The positive carbon, which is soft-cored and larger in diameter than the negative, has its crater towards the reflecting mirror. A small disc metal reflector perpendicular to and over the positive carbon also aids in reflecting scattered rays to the larger mirror. Two similar projectors are placed on the bridge deck aft and are operated from a platform under the bridge deck. Each projector is supplied with a Weston volt and ammeter, as well as a rheostat, which are located in the dynamo-room in a convenient position for the man in charge to handle. To the right of the bridge helm is an instrument called the helm indicator, forming a part of the Fiske system of ship telegraphs. It indicates the position of the helm at any instant, and is in principle merely a galvanometer, having its zero point in the central vertical position, and connected in parallel with a circuit such as shown in Fig. 1. Rigidly fastened to the rudder-post is a strip of resistance wire, through which a current from the main lighting circuit continually passes. As the rudder moves, a contact simultaneously slides over this resistance which cuts in or out more or less of it and therefore produces a corresponding change in the difference of potential at each indicator. These indicators are placed in various parts of the ship and are illuminated each by a small incandescent lamp.

Directly in front of the bridge helm is the compass, of the navy ordinance pattern, and to the left of this is the steering telegraph, the function of which is to telegraph to the steering wheels the position at which the officer in charge desires to have the helm placed. This transmitter, which is but one of several, is electrically

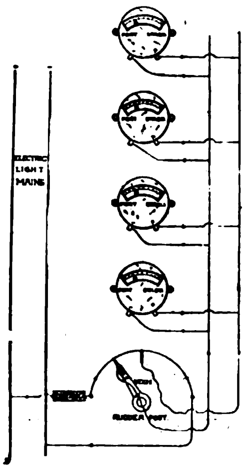

Fig. 1.—Connections for Helm Indicator.

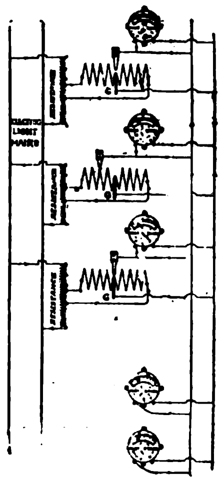

Fig. 2.—Connections for Steering Telegraph.

connected to indicators secured in conspicuous positions near the steering wheels and operated upon the same principle as the helm indicator just described. A diagram of the connections is shown in Fig. 2, where G represents the transmitters, which are located on the bridge, directly under the bridge in the pilot-house and directly under the pilot-house and within the mast, called the conning tower. In fact, the entire management of the ship

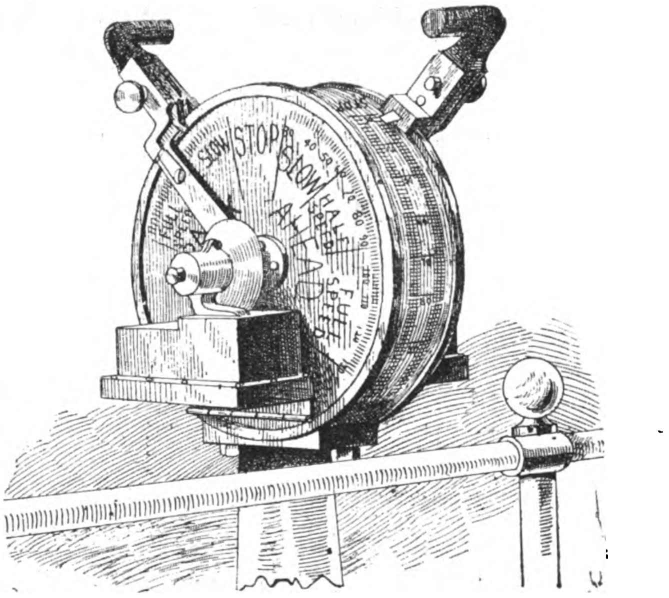

Fig. 3.—Engine Telegraph Transmitter.

can be controlled from either of these positions, the latter, which is heavily armoured, being used only in practice or an engagement. The movable contact of the transmitter, G, does not touch when in the central position, in which position it remains when not being used, so that any transmitter is independent of the others and may be used at any time.

After the command has been given to set the helm at a certain position indicated by all of the steering indicators, the precision with which the man at the helm obeys is

* From the *Electrical World* (New York).

Digitized by Google

immediately recorded by a helm indicator placed near the former.

Fastened to the mast a few feet above the bridge is a speed and direction indicator having a port and starboard needle, which are respectively operated by the port and starboard engine shafts. This indicator is for the purpose of telling in which direction the shafts are running, and with the aid of a watch the number of revolutions may be determined. In principle the indicator is exceedingly simple, being merely a polarised relay. It is operated by a toothed eccentric strap fastened to the shaft and rolling, on which is a small tooth roller. As the shaft turns the

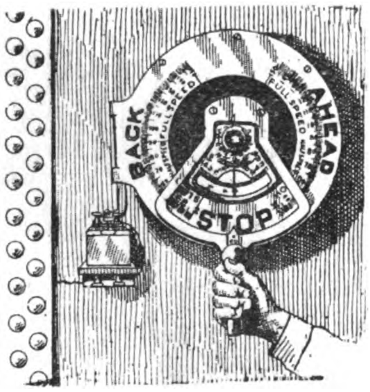

FIG. 4.—Engine Telegraph Receiver.

roller is shifted slightly, depending upon the direction of rotation, and at the same time raises at each turn a contact point which makes contact at either the right or left, thereby determining the direction of the current through the indicator at the bridge.

Another and far more important instrument to be found on the bridge is the Fiske engine telegraph. The function of this instrument is to signal to the engine-room the desired speed and direction of the engines. Each engine has its transmitter and receiver, the transmitters being in one instrument (Fig. 3) and one receiver (Fig. 6) in each engine-room. The telegraph is operated on the Wheatstone bridge principle, as shown in Figs. 5 and 6. Both the transmitter and receiver have equal resistances arranged in an arc of a circle. The zero position of each instrument is vertical. It

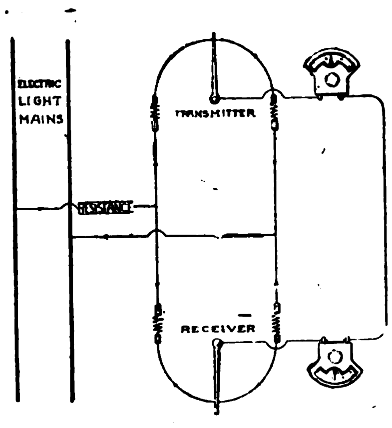

FIG. 5.—Sketch showing the Principle of the System of Telegraphs.

follows, therefore, that if the transmitter handle be moved over a given arc it will be necessary, in order to balance the bridge, to move the receiver handle a corresponding amount. In series with both the receiver and transmitter are galvanometers—that on the former being a Weston instrument. After the transmitter handle has been thrown over both galvanometers will deflect, and will continue to do so until balanced at the receiver. Thus the officer giving the command knows immediately if his order has been received. The Weston instrument, placed on the receiver, moves with the handle, and inasmuch as the needle is not balanced for all positions, it is necessary to have a second stationary galvanometer (shown at g^1, Fig. 6) to make more exact adjustments. This is done by shifting the handle and tapping the key A. Moving the arm of the transmitter over a very small arc automatically rings a 10in. gong located in the engine-room, thereby attracting the engineer's attention.

It will be seen in Fig. 3 that the engine telegraph has two handles. The two sides are duplicated, and transmit respective orders to the port and starboard engine-rooms. Placed at each side is a small 1-c.p. lamp to illuminate the faces at night. The whole system is operated by taking a drop across the lighting mains. The graduations on both the receiver and transmitter correspond to revolutions per minute.

There are two systems of night signalling used in conjunction with the electric lighting system. The truck light consists of a double lantern placed at the top of the mast, the upper half of the lantern being red, the lower white, in each half of which an incandescent lamp is placed. These lights are operated separately or together by means of a pulsating switch situated on the forward part of the mast on the top of the pilot-house. This signal is for the admiral's use in squadron evolution.

The second is called the Ardois signalling set, and is composed of four double lanterns, upper red, lower white,

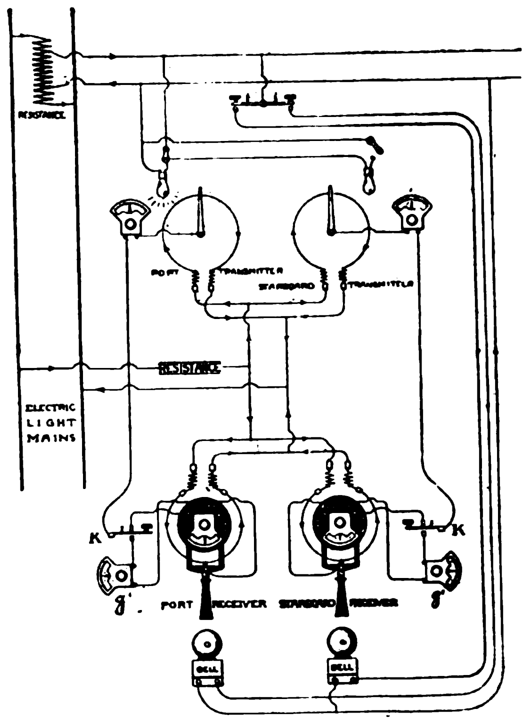

FIG. 6.—Diagrammatic Sketch of Engine Telegraph Connections.

having Fresnel lenses. These lanterns are suspended by two wire jack stays with connecting cross-arms, from the centre of which the lanterns hang, spaced 10ft. apart. The upper end of the jack stays is secured aloft to a stay, and the lower end sets up with two turn-buckles, one on each leg. There is a cable containing a wire for each lamp with a common return, which is connected electrically to a key-board (Fig. 7). The face of the board is divided into sections; each one of these sections is marked with the number and order in which the lanterns will burn when the key is moved to this section. These sections designate numerals, letters, or sentences. By this system it is possible to form 64 combinations. The type of lantern used is shown in Fig. 8.

Passing from the bridge to the pilot-house an addition to the instruments already described is one for automatically blowing the whistle at stated intervals. It is simply a clock arrangement operating an electric contact, completing a circuit which in turn operates by means of a magnet a lever attached to the steam whistle. A telephone also runs from the pilot-house to the "central station," where it is connected to the desired circuit.

The Fiske "range finder," one instrument of which is situated just above the bridge and the other on the bridge deck aft, 42⅝ yards apart, consists of two pedestals, on

Digitized by Google

each of which is mounted a telescope with cross hairs, also an indicating instrument placed in the conning tower, consisting of a Deprez-d'Arsonval type galvanometer, manufactured by the Weston Instrument Company. The graduations on the galvanometer are in yards. The observers at the two telescopes are connected by telephone with each other, and with the observer at the indicating instrument. The operation of these instruments is also based on the Wheatstone bridge principle, but instead of employing resistances in the form of arcs of circles, the resistance wire is wound upon cylinders which, by means of proper gear, revolve simultaneously with the lateral movement of the telescopes. This method allows of correcting for inequalities in the resistance wires. When the two telescopes are parallel, and the circuits are in correct adjustment, the reading instrument, located in the conning tower, points at infinity. An adjustable resistance is in series with the voltmeter, so that if the E.M.F. of the storage battery supplying the circuit changes or the resistance of the indicator changes, due to temperature effects, the same may be corrected.

Upon pointing the two telescopes upon the same object the indicator needle is deflected and will indicate the distance in yards, and the object is from a position on the base line halfway between the two instruments. Space will not permit of showing how the indicator is graduated, it being done, however, by a simple trigonometrical process. Similar range indicators are located at the various guns,

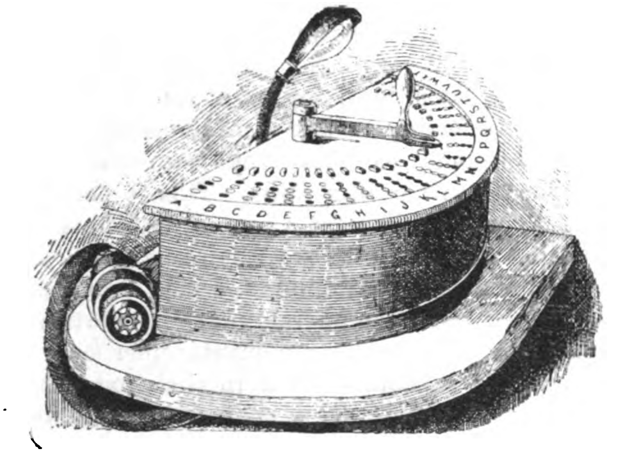

FIG. 7.—Keyboard of Signalling Set.

the entire firing of which is directed from the conning tower.

The 8in. gun turrets have electrically-operated hoists for lifting ammunition from the lower deck to the gun breech. These equipments were furnished by the General Electric Company. In the 13in. gun turrets two Lundell fan motors are used to blow the smoke out.

The dynamo and engine room contains three navy standard marine generating sets composed of three 24-kilowatt G. E. compound-wound dynamos, connected direct to three G. E. navy standard marine vertical double-cylinder engines. The units run at 400 revolutions per minute, and deliver each 300 amperes at 80 volts. The switchboard is designed for 22 circuits, 20 now being in use. There are two switches for the lighting circuits, four for searchlights and six for ammunition hoist motors. The switches are arranged so that each can be thrown on one of the three dynamos; the board is also provided with three parallel switches for throwing dynamos in parallel when necessary. There are two instrument boards, one on each side of the switchboard, the one on the left having two Weston station voltmeters, ground detector lamp, and switches; one voltmeter is used for the lighting and motor circuits, the other for the searchlights. The instrument board to the right has mounted upon its face three Weston astatic ammeters, one for each machine. The ship is supplied with the necessary electrical testing instruments, consisting of one 20,000-ohm magneto, one Evershed testing set, comprising one portable hand generator and ohmmeter. There is also supplied for testing one hand tachometer, one hand speed indicator, and three Tabor engine indicators. There are 615 incandescent lights installed on the ship with the necessary watertight feed and junction boxes, switches, and receptacles. Two running lights or lanterns are attached to the mast, the upper one being the mast headlight and the lower is used with the upper when towing. The side lights are composed of two stationary lanterns—one on the port and one on the starboard side of the vessel. These lights are burning only when the ship is motion. When the ship is at anchor there is a lantern hung on a halyard halfway from top of mast to bow, also a lantern at the stern, and a lantern swung out by means of a boom over each propeller. The lights are distributed throughout the ship by means of two sets of circuits—one being the lighting circuit, the other the battle circuit, which is only used when the ship is in action.

The fixtures are all of the navy standard pattern. They are all of a specially watertight type, and are composed of battle lanterns, hand portables, deck lanterns, desk lights, bulkhead fixtures, cargo reflectors, and electroliers. In the officers' quarters the fixtures are all silver-plated. The wire used for this work is of the navy standard, and was furnished by the Safety Insulated Wire and Cable Company, New York. Taking all the different sizes there is about seven miles of wire and about 3½ miles of wood

FIG. 8.—Ardois Lamp.

moulding for the same. The wires are all in moulding, and are very thoroughly insulated, being carried through rubber tubing at each beam, the beams being 4ft. apart, and through watertight stuffing-tubes at each watertight bulkhead, or where the wires pass through decks.

There is a complete set of fire and water alarms throughout the ship. The electric thermostats consist of an iron thimble containing mercury, and provided with a non-combustible fibre cork. Through the latter is a small screw passing down through a glass tube. By turning the screw the thermostat may be set for any desired temperature. Upon heat being applied to the thimble the mercury rises and makes contact, which indicates on an annunciator placed aft. The water alarm consists simply of a float, which rises and completes an electrical circuit when the water in that particular department attains a certain height.

A telephone system consisting of 24 Claymond telephones and a "central station" is one of the features. Speaking-tubes with buttons and annunciators are run from all principal points to the central station and conning tower. The central station is located in the forward part of the protective deck inside of the armour belt. Lieutenant Fiske's apparatus was made by the Western Electric Company, and with the exception of the range finder was installed, together with the annunciator, fire alarm, revolution counters, etc., by Messrs. Charles Cory and Son, New York.

From the foregoing description it will be seen that electricity now plays a most important *rôle* in modern naval engineering.

MUNICIPAL APPOINTMENTS.

The general tendency in this country towards municipal ownership has already provided appointments for a large number of electrical engineers. There are also signs that electric traction will in many towns be kept in the hands of the authorities, and that for this department also a number of engineers will be required. Amongst the first municipal appointments in electric traction work to be filled is that of clerk of the works at Leeds. We notice elsewhere in our columns the fact that the committee has decided to appoint a man whose extensive experience in similar work elsewhere warrants the support he received. It is an appointment made on the merits of the case, coupled, however, with a consideration of the salaries asked by the various competitors. The only point on which we understand that some of the unsuccessful applicants feel aggrieved is that the salary should have had so large an influence on the committee's decision. The five engineers selected to appear before the committee all asked for different salaries, which varied by over 150 per cent. The candidates were given to understand that the gentleman who should be chosen to act as clerk of the works during construction would most likely be appointed engineer afterwards. This fact may have had a great influence on the candidates in fixing what salary to ask, some men preferring to ask a small salary for the first appointment, so that they may make sure of the good position afterwards. This is perfectly justifiable, but hardly what a committee wants. A corporation can afford to pay a fair salary for work done, and should, in our opinion, decide beforehand what is the fair remuneration for a particular appointment. Then the applicants differ only in their personal capabilities and in their experience of the work required. This course simplifies very much the process of selection, and tends toward an adequate remuneration being given to technical officers. It is much better for all concerned that such salaries should be fixed with regard to the capital expenditure involved, and not to the lowest figures at which the work can be done. When this is done, we shall not have the continual moving of prominent officials so much in evidence lately. Another feature of municipal appointments we have often referred to is that of the relationship between the engineer and his committee. In most towns, after the supply has been commenced, the engineer prepares plans for extensions and superintends this department of the work. All his proposals, however, are considered by his committee, and it is not an unknown occurrence for work to be considerably delayed in consequence. Still, it is the engineer's duty to keep the authorities in touch with all that concerns the welfare of his department, and above all in electricity work to keep up the regularity of the supply. Any small defect arising in the system should, of course, be promptly attended to, but the engineer must not allow the matter of large repairs or renewals to demand sudden attention without warning those to whom he is responsible. We believe that this consideration has prompted the Blackpool report, which we print in another

Digitized by Google

column. The new engineer has seen what he considers to be grave defects in this system of mains, which, coupled with a depreciation of the insulation, may interrupt the supply. Other matters in connection with the economical supply in his opinion calls for alteration, and consequently some parts of the report will not be pleasant reading to those who have had to do with this station in the past. The engineer in question has laid himself open to the usual taunt of being "a new broom," but we are glad to hear that the report has been accepted by the Corporation, and that the defects will be speedily remedied. This support will encourage the engineer in the arduous task before him, and we trust that the necessary alteration will be made without prejudicing the supply. There is one feature in the report of which we do not approve, and that is of recommending that certain plant should be ordered from a given firm. All such orders for extension should be open to competition, and the competition should be as little influenced as possible by the preference of the engineer for a given type.

"PRACTICABLE" AND "PRACTICAL."

BY F. M. WEYMOUTH.

It is, perhaps, one of the most common mistakes of the day not to distinguish between what is practical and what is practicable. So many curious things, at any rate, have come under the writer's notice in this direction at various times, resulting more or less from a confusion of these terms, that he is led to believe some remarks on the subject may not be amiss. It is a clear conception of the difference between these terms which is apparently so often wanting in many minds.

We may perhaps, then, best commence, rather than by enunciating any particular definitions, by illustrating the problem with some general example. Suppose, for instance, anyone desired to travel, say, from Westminster to the City. A host of methods of travel may all be practicable. He may go by a balloon, or be hoisted by kites, or even with ladders clamber over the housetops. But more practical ways are to take a train, cab, or 'bus, or to walk. We thus see that while many ways of doing a thing may be practicable, all are not practical A certain point, indeed, is at once foreshadowed—namely, that unpractical ways are frequently absurd, though yet practicable, the pity being that the absurdity of some enterprises as wanting in sensibleness as any of the above is not perceived by those responsible. But, keeping to our illustration, we may note that the term practical is a comprehensive one, and includes within its meaning various specific qualities. Thus, besides sensibleness, or what is popularly known as "common sense," time and cost may be considered. The cheapest way, obviously, if time is less an object, is to walk, while a 'bus will give the cheapest ride. If time is more an object, then it is a matter of experience or computation whether a cab or the train will be the quicker; in short, it may be said that the term practical applies when in the accomplishment of any object such as the above, before it is attempted, all points of consideration are duly thought about beforehand, so that the particular method of procedure finally decided on shall be the most reasonable and the best. This may then be termed the "practical" method, as compared with any others, which, howsoever absurd, may yet be "practicable."

But to come from generalities to what is more technical, we may observe that in electrical and engineering work it is in matters of construction that perhaps most frequently we want to know what is practical. Here again, then, to quote an example by way of better illustrating our argument, we may draw attention to the difference between the locomotive on the road and that on the rail. The former, usually known as a traction engine, has toothed gearing, while the latter has not. Yet it would be quite practicable to reverse the order and put a geared locomotive on the railway and one direct acting without gear on the road. But "practical considerations" do not commend such reversal. The railway is perfectly smooth, has no sharp turns, and is laid with comparatively slight gradients. The road, on the other hand, is liable to be rough and undulating, has sharp turns round street corners, and so forth, and has steep gradients. Moreover, a high speed is required on the rails and a slow speed on the road. It is, thus, for all these "practical considerations" that we find these classes of locomotive so different in design. On the road, in order to overcome the momentary and intermittent resistances due to its roughness, and to maintain evenness of speed, a quickly revolving flywheel is necessary, that by means of its stored-up energy such resistances may be at once overcome and an even speed maintained. Two or more changes of speed in the gear will also enable great variations of gradient to be easily dealt with. These difficulties not being present in the case of an ordinary railway, flywheels and gear are not needed, and though gear was used in early days, if added in these modern times without special reason, it would merely constitute an unnecessary and unwarranted complication.

Let us look, however, at some electrical work. Switches, for instance, deserve some attention, also the brush gear of dynamos and motors. How many switches have we not seen which after a little use have become loose and "ramshackle." Their construction has been quite practicable, plainly, but their "practicality" is quite another thing. That kind of switch, for instance, whereof the rotating part is a stalk, whose lower end is fitted into a single socket in the base, and the moving contact-making arm protrudes from, or passes through, the stalk just above the socket, while an obliquely-disposed handle is led off from the top. Such a switch, say about 6in. in diameter, is put to control a motor. What is the result? A workman's heavy hand is continually on the outer end of this handle, and every time the switch is used the lower end of the stalk is ground round in its socket with this great one-sided leverage. The result is that the socket is soon worn larger than the stalk, so that the latter can then "wobble," being no longer properly held. Taper sockets have been used, but fit is apt soon to go. Yet a design of switch which takes all this heavy-handed manipulation into account is not at all impossible. Thus a switch designed for strength, and made perhaps a little larger than absolutely required for the current, and, what is more to the point, made with bearings at both ends of the stalk instead of the single socket, would endure far more wear and be proportionately more "practical."

We may now touch on a curious point in connection with brush gears. It would seem that the early electrician, after the flying to pieces of some armatures owing to neglecting centrifugal force, and so forth, was glad of the aid of the mechanical engineer in constructing dynamos and motors, but always reserved one thing—the brush gear. But in this reservation, as we shall show, the early electrician made a mistake; for he introduced a very unpractical thing in his design which has remained ever since. We allude to the method of applying the tightening springs for keeping the brushes up to their work; for in most cases we find these springs arranged so that they act tangentially with the commutator at the point of contact, the consequence being that as the brushes wear they are pulled away from their proper position. The slope of the brushes and the angle of the contact ends are both altered. It is thus rendered necessary to entirely reset the brushes many times before they are used up. We hence find here another instance in which a design has not been so "practical" as it might have been. A more practical design, inasmuch as such effects are easily to be foreseen, would avoid this trouble in usage, and so would have it arranged that while the brushes were kept up to their work, and fed up as they wore, yet the means for so doing should not draw them away from their proper position, nor alter their angle with the horizontal. This little point has apparently, however, been receiving some attention, and we note that the Admiralty have been demanding brushes with forward thrust.

Digitized by Google

We have thus to observe that in matters of construction the term "practical" includes the condition that all parts must be designed and put together with a due regard to the stresses and strains in each part. It will, however, also include the use of proper materials. Metal or other material must be properly "placed," and not a great mass put where there will be scarcely any strain, and only a little material where the strain will be great—cases of ineptitude in design by no means unknown. An instance may be cited of an armature spider cast with enormously thick radial ribs, involving great waste of gunmetal, and yet with an end plate cast on one end so thin that it deflected when the core discs were tightened against it by a nut at the other end.

A few examples only have been given above. Many more might be added. We may merely conclude by remarking that it would probably be a surprise to many were it better known, especially when these errors occur on a large scale, how many disappointments and failures of enterprise have resulted simply from a want of a proper appreciation of the very wide difference between "practicable" and "practical."

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.SC.(EDIN.), A.I.E.E.

(Continued from page 234.)

50. Since an alternating P.D. or current varies from instant to instant, it is at once evident that if we are

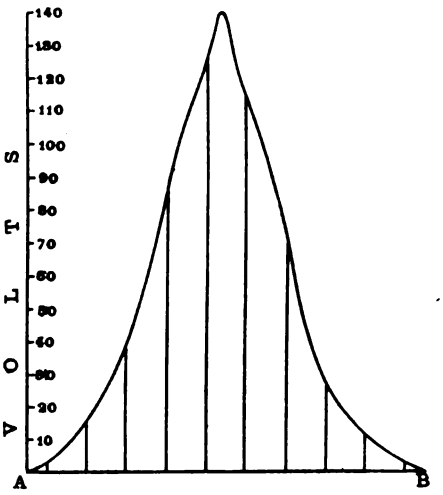

Fig. 44.

to measure such a varying quantity, it becomes necessary to define exactly what we mean when speaking of *one volt of alternating P.D.*, or *one ampere of alternating current.* Since the waves of P.D. and current which we are considering are supposed to be symmetrical with regard to positive and negative half-waves, it follows at once that the mean *algebraical* value of the P.D. or current over any complete number of periods is nothing. We are not, however, concerned with the mean algebraical value, for this gives us absolutely no clue as to the magnitude of the current. In some cases it is important to consider the mean *numerical* value of the current over a complete period, or, which comes to the same thing, its mean value over a positive or a negative half-period. In order to determine this value, we may adopt the method used by engineers in working out the mean pressure from an indicator diagram. Thus, let the curve in Fig. 44 represent a positive half-wave of P.D. In order to determine the *mean value* of the P.D., divide the half-period A B into a convenient number of equal parts,† and at the middle point of each division draw a perpendicular to the axis of time. By taking the sum of the lengths of these perpendiculars and dividing by their number, we obtain the mean value of the P.D. In the example under consideration (Fig. 44) we find that the lengths of the perpendiculars are

3, 15, 39·6, 86·4, 126, 115·5, 69·6, 27, 11·4, and 3

respectively. Hence the mean value is

$$\frac{3+15+39{\cdot}6+86{\cdot}4+126+115{\cdot}5+69{\cdot}6+27+11{\cdot}4+3}{10}$$
$$= 49{\cdot}65 \text{ volts.}$$

A knowledge of the mean value of a given E.M.F. wave is of importance in the design of alternators, for it is this value which is calculated most readily. As a typical example, let us suppose that an alternator field magnet consists of a frame furnished with polar projections, as shown in Fig. 45, the projections being of north-seeking and south-seeking polarity alternately. Let C C′ be one of the alternator armature coils, of S turns, and let us suppose that in t seconds this coil is carried from its initial position (opposite a north-seeking pole) to the position shown dotted (opposite the neighbouring south-seeking pole). If N stand for the total number of C.G.S. lines which proceed from each pole, the change in the number of lines through each turn of the coil is from + N to - N—*i.e.*, the total change amounts to 2 N. Since the change has taken place in t seconds, the E.M.F., in C.G.S. units, induced in each turn of the coil amounts to $\frac{2\,N}{t}$. Hence the total E.M.F., in volts, induced in the whole coil is

$$\frac{2\,N\,S}{t} \times 10^{-8} \text{ volts.}$$

If there are n coils connected in series in the armature winding, then the total *mean* E.M.F. of the alternator is the above expression multiplied by n. It is thus quite easy to calculate the *mean* E.M.F. developed by a given alternator when the magnetic flux from each pole and the speed are given.

51. In other cases, again, the quantity which it is important to know is the *maximum* value of the E.M.F. In the case of power transmission by means of high-potential alternating currents, the insulation of the line, transformers, etc., must be sufficiently good to withstand the greatest stress to which it may be subjected. But the latter depends solely on the *maximum* value of the E.M.F.

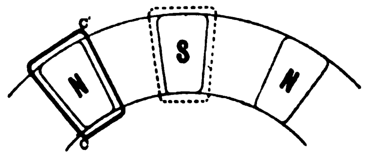

Fig. 45.

employed, so that in this case we are concerned with the *maximum* value, and not the mean value. From this point of view it is evident that, *apart from other considerations*, a *flat-topped* E.M.F. curve is to be preferred to a *peaked* one; for the latter puts a greater strain on the insulation than the former.

52. In most cases, however, it is neither the *mean*, nor yet the *maximum* value of the varying quantity which concerns us most. We now proceed to explain the nature of the quantity which is generally considered in all alternate-current measurement. Take the case of an incandescent lamp supplied with an alternating current. The amount of light given out by the lamp will obviously depend on the *heating effect* of the current. Now as the current varies, its heating effect will also vary from instant to instant. At any moment, however, *the heating effect will be proportional to the square of the corresponding value of the current.* Let in Fig. 46 the full-line curve A D B represent the curve of current. The dotted curve A E B is such that its ordinates are equal to the squares of the corresponding ordinates of A D B. Thus, the corresponding points D and E are so related that $CE = CD^2$. It follows from this that if A D B represent the variations of the current, A E B will represent the variations in the heating effect produced by the current. In order to determine the *mean heating effect*, on which the total amount of light given out by the lamp depends, we

* Based on a series of evening lectures delivered at the University College, Liverpool.

† The greater the number of divisions, the greater will be the accuracy obtained.

Digitized by Google

must find the mean ordinate of the curve A E B. This is readily done by the method explained above (Art. 50). The mean ordinate of the curve A E B gives us the *mean value of th? square* of the current, or, briefly, the *mean square* of the current.

Let us next suppose that the same lamp is supplied with a continuous current which produces *the same heating effect* as the alternating current. In order that this may be the case, it is obvious that the square of the continuous current must equal the mean square of the alternating current. So that for equal heating effects we must have the relation

(continuous current)^2 = mean square of alternating current,

i.e, continuous current = $\sqrt{\text{mean square of alternating current}}$.

The inductance of an incandescent lamp is so small that it may be neglected, so that the impedance is practically equal to the resistance of the lamp. From this it follows that the current at any instant is simply equal to the quotient of the P.D. by the resistance. Hence the current wave will have precisely the same shape as, and be in phase with, the P.D. wave, and it follows that if instead of considering currents we consider P.D.'s, then for equal heating effects we must have

continuous P.D. = $\sqrt{\text{mean square of alternating P.D.}}$

Whether, therefore, we consider current or P.D., the important quantity from the point of view of the heating and lighting effects is *the square root of the mean square value.* For the sake of brevity, this latter quantity is generally referred to as the R.M.S. ("root mean square") value.

53. When we speak of so many volts of an alternating P.D., or so many amperes of an alternating current, we

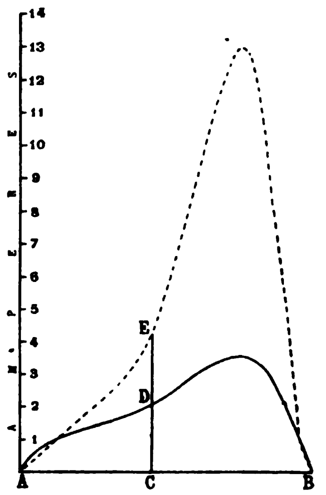

FIG. 46.

thereby mean their R.M.S. values. We thus have the following definitions:

An alternating P.D. of one volt [alternating current of one ampere] *is a P.D.* [current] *whose R.M.S. value is unity.*

A unit alternating current might otherwise be defined thus:

An alternating current of one ampere is an alternating current which, in a given conductor maintained at a constant temperature, produces heat at the same rate as that at which it would be produced in the same conductor under the same conditions by a continuous current of one ampere.

The student must be careful to discriminate between the R.M.S. and the *mean* values. Referring to Fig. 46, we find that the mean value of the current is 2·06 (which is the mean value of the ordinate of the curve A D B). The value of the mean square of the current (which is given by the mean ordinate of the dotted curve A E B) is 5·22, so that the R.M.S. value of the current is 2·28.

A knowledge of the relation between the R.M.S. and the mean values of a wave is of very considerable importance in some cases. Thus, let us suppose that we have to design an alternator of a certain type to give 100 volts at a given speed. By the 100 volts is meant the R.M.S. value of the E.M.F. Now the quantity which is directly calculable from the known dimensions and speed of the alternator is *not* the R.M.S. value, but (Art. 50) the mean value. It is thus necessary to know the relation between these two quantities for the given type of alternator before the calculation can be carried out. Dr. Fleming has proposed to give the name "form factor" to the ratio of the R.M.S. value to the mean value. The *form factor* varies in different types of machines from about 1·1 to about 1·4. If the form of the E.M.F. wave is known, then we can at once determine the *form factor.* Thus, we have found that the mean value of the ordinate of the E.M.F. curve, shown in Fig. 44, is (Art. 50) 49·65. In order to find the R.M.S. value, we first of all determine the mean square. This is done by squaring the lengths of the 10 ordinates, which gives us the numbers

9; 225; 1,568; 7,465; 15,876; 13,340; 4,844; 729; 130; and 9,

so that the mean square is 4,419·5, and hence the R.M.S. value is $\sqrt{4{,}419} = 66{\cdot}5$ volts. The *form factor* for this type of wave is therefore $\frac{66{\cdot}5}{49{\cdot}65} = 1{\cdot}34$.

54. We have next to consider the *measuring instruments* which may be used on alternate-current circuits.

An alternating P.D. may be measured by means of a Cardew or an electrostatic voltmeter. The readings of both these types of instruments are determined by the R.M.S. value of the P.D. In the case of the Cardew voltmeter, the reading of the instrument is determined by the heating effect produced by the current. Owing to the extremely small inductance (Art. 31) of the instrument, the current is in phase with the P.D., and is at any instant equal to the quotient of the P.D. by the resistance of the instrument. From this it follows that an alternating P.D. whose R.M.S. value is E volts will produce a current through the instrument whose R.M.S. value is equal to the continuous current produced by a continuous P.D. of E volts. But (Art. 52) an alternating current whose R.M.S. value is equal to a certain continuous current produces the same heating effect as this continuous current in a conductor of given resistance. Hence an alternating P.D. whose R.M.S. value is E volts will give the same deflection as a continuous P.D. of E volts, so that *a Cardew voltmeter which has been calibrated with continuous P.D.'s will read correctly when placed on an alternate-current circuit, and the quantity which it measures is the R.M.S. value of the P.D.*

Considering next the case of an electrostatic voltmeter, it will be readily seen that since for a given position of the moving part of the instrument the couple acting on it is proportional to the *square* of the P.D., the deflection produced by an alternating P.D. whose R.M.S. value is E volts will be the same as that produced by a continuous P.D. of E volts; for the mean couple in the first case is the same as the steady couple in the second. Hence an electrostatic voltmeter calibrated with continuous P.D.'s will correctly read alternating P.D.'s.

Electrodynamic and electromagnetic voltmeters are not very suitable for alternate-current circuits, and hence they are not much used on such circuits. Owing to the inductance of the coil of such an instrument, the current which passes through it is only a small fraction of that which would be obtained with a continuous P.D. of the same amount,* so that voltmeters of this kind have to be calibrated by using known *alternating* P.D.'s. Further, since the current passing through the voltmeter depends on the impedance of the coil, and therefore on the periodicity, an instrument calibrated on a circuit of given periodicity will not be correct for another circuit whose periodicity is different. To give the student some idea of the effect produced by the inductance of the voltmeter coil, it may be mentioned that in the case of a voltmeter of the Ayrton and Perry magnifying spring type, a P.D, which, if steady, gives the maximum scale reading, will, if alternating with a periodicity of 100 ∿ per second, produce a deflection which is not even readable on the scale.

The most satisfactory instruments, from every point of view, for measuring alternating P.D's are those of the

* Unless a large non-inductive resistance be connected in series with the voltmeter coil, so as to make the impedance practically equal to the resistance; in that case, however, the current is also greatly reduced, and the controlling couple must be diminished.

Digitized by Google

electrostatic type, and these will probably altogether displace instruments of other types.

55. An alternating *current* may be measured by a Siemens electrodynamometer, a Kelvin balance, or an electromagnetic ammeter. The first two instruments named will read the R.M.S. value of the current correctly on an alternate-current circuit if previously calibrated with continuous currents. But an *electromagnetic ammeter* which has been calibrated with continuous currents will *not* read correctly on an alternate-current circuit, and must be specially calibrated with alternating currents of the same periodicity as that of the circuit on which the instrument is to be used.

(To be continued.)

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 232.)

The special apparatus for ensuring safety of working already described has been of a partial character only, and adapted to meet given circumstances. Figs. 55-66 illustrate Saxby and Farmer's union of the locking apparatus of the mechanical signals with the block signalling apparatus, and constitutes a more complete attempt to meet all the contingencies which can be foreseen. The objects aimed at in the design, besides the ordinary block signalling, are (*a*) the locking of the instrument handle at the receiving end of the section, until the train signalled has passed a pre-arranged point at that place; (*b*) the locking of all points and signal levers, the operation of which involves fouling of the running line, for all positions of the block instrument handles, except the normal position, when the section is unoccupied; (*c*) the locking of the "starting" or "advance" signal to danger for all positions of the block indicators except "Line clear;" (*d*) ensuring the raising of the signal to danger when it is no longer required to be "off" for the train signalled, and accepted, to proceed. The block indicator and signalling apparatus follows the usual line of design for single-wire instruments, and consists of a ringing and signalling plunger, a commutator for reversing the direction of the currents sent, the electromagnets for working the semaphore indicators, a relay, and a bell. All signals are given by the plunger, and the direction of the currents so sent is controlled by the position of the handle of the instrument. Currents pass through the electromagnets actuating the lower semaphore indicator at the home station, and through the upper electromagnets at the distant station. The non-polarised relay is actuated by all currents, and the bell is rung accordingly. In connection with the upper semaphore arm is a mercury contact switch, which makes or breaks a circuit passing to the starting signal according as the semaphore arm is down or up. A similar switch is worked in connection with the mechanism provided for locking the handle of the block instrument. This switch completes a circuit through the handle-releasing coils and a rail treadle which brings them into action, when the handle is on the "Train on line" position, and breaks the circuit when the handle occupies either the "Line clear" or "normal" (line blocked) positions. Besides these two switches there is an electromagnetic two-way mercury contact switch, in a separate case, which is used in connection with the working of the starting signal.

Fig. 55 is a side view of the instrument with the case removed, and shows the general arrangement of the indicator electromagnets, A, the handle-releasing coils, B, the ringing and signalling plunger, P, the commutator, H, and the switch, S, in connection with the upper semaphore arm. Fig. 56 shows the mechanism for locking the commutator handle in the "Train on line" position after it has occupied the "Line clear" position, and also shows the mercury switch, S_1, in connection with the releasing circuit. Figs. 58, 59, and 60 show the various positions of the handle-locking mechanism for the "normal," "Line clear," and "Train on line" positions respectively. The curved lever, L, is raised when the handle is placed to "Line clear," and a small stud, shown in dotted lines in Fig. 58, engages with the projection of the armature of the releasing coils, B (Figs. 55 and 56), and is held there until the armature is attracted, which takes place when the train passes over the rail treadle provided for closing the circuit. The same movement causes the shaded disc, F (Fig. 58), to appear at the opening, N (Fig. 57), in the front of the instrument.

Fig. 57 shows the arrangement of the commutator. As shown, with the handle in the "Line blocked," or normal position, the depression of the plunger puts the springs, *a* and *b* in contact, and also springs *c* and *d*, and at the same time breaks contact between *c* and *e*. The current so sent does not affect the indicators at either station, and the only effect is to ring the bell. When the handle of the

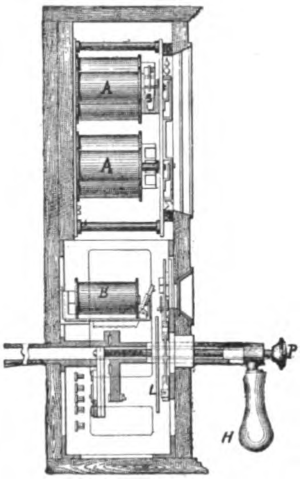

Fig. 55.

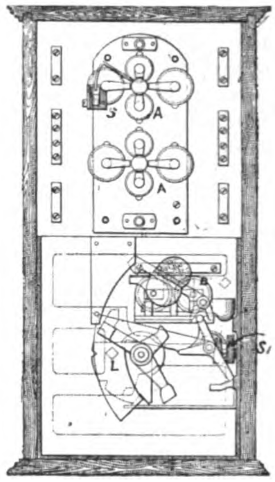

Fig. 56.

commutator is placed to "Line clear," depression of the plunger connects springs *a* and *d* and *b* and *c*, and breaks contact between *c* and *e* as before. The direction of the current is now reversed, and the lower semaphore arm at the home station and the upper semaphore arm at the distant station are lowered, and indicate "Line clear." When the handle is in the midway, or "Train on line," position, depression of the plunger effects the same combination as when in the normal position, and the currents so sent raise the lower arm at the home station and the upper arm at the distant station to horizontal positions. Fig. 61 shows a plan and

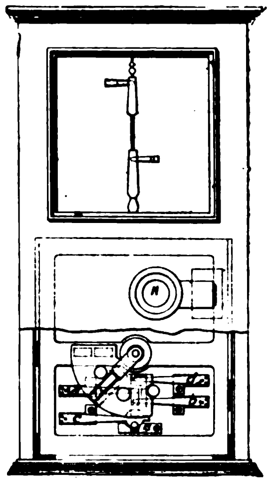

Fig. 57.

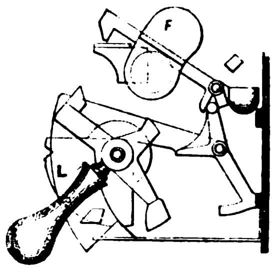

Fig. 58.

front elevation of the special mercury switch used in connection with the electrical control of the starting signal, and Fig. 61A shows a side elevation of the same. Fig. 62 shows the method of locking the levers of fouling points, etc., with the handle of the block instrument in the "Line clear" and "Train on line" positions. Conversely, the handle of the block instrument is locked in the "Line blocked," or normal position, when these levers are being operated.

Figs. 63, 64, 65 show the operation of the electrical control of the starting signal, and Fig. 66 is a diagram of the connections for one complete block circuit. The form

Digitized by Google

of rail treadle used in connection with the system is shown by Figs. 39 and 40.

The operation of the instruments for signalling is very similar to that of some of the instruments already described, and need only be referred to very briefly. The "Is line clear," or equivalent signal, is given from the sending end with the handle in the "Line blocked" position. If the signalman at the receiving end is in a position to accept this signal, he first moves the handle of his instrument to the "Line clear" position, and gives the appropriate accepting signal. The semaphore arms are lowered at both stations, as already described, by the accepting signal, and remain in this position, indicating "Line clear," until further signals are exchanged. It will noted that owing to the locking of the handle of the instrument by the mechanism shown in Fig. 56, the ability to place the handle to "Line clear" is proof that the previous train has passed over the handle-releasing treadle, and owing to the interlocking of the block instrument handle with the levers controlling fouling points, the ability to move the handle from the "Line blocked" position is proof that the line is clear of

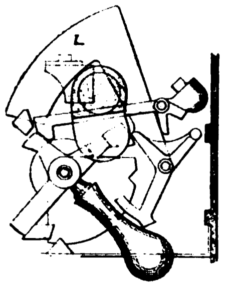

Fig. 59.

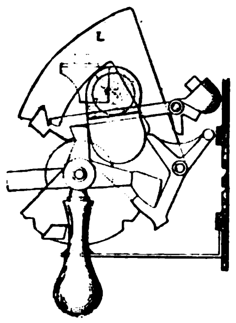

Fig. 60.

shunting or similar operations. Further, the act of placing the handle to "Line clear" raises the curved lever, L, until it engages with the armature of the releasing coils. Once in this position the locking mechanism prevents it being replaced in the "Line blocked" position until after the armature of the releasing coils has been moved. This, of course, under normal conditions, is done by the passage of the train over the treadle, but it should also be noted that the passage of a train over the treadle during the time the handle is to "Line clear" will not actuate the armature of the releasing coils, owing to the switch, S_1, being open in that position. S_1 is only closed when the handle is in the

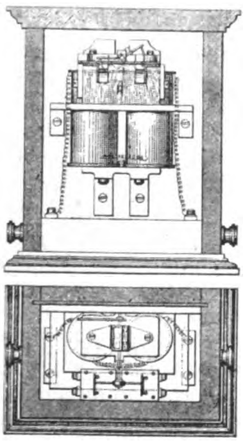

Fig. 61.—Electromagnetic Mercury Contact Switch for Controlling Outdoor Signal.

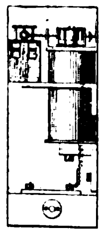

Fig. 61a.

"Train on line" position. The lowering of the upper semaphore arm at the sending end causes a local current to be established which passes from the battery, D, through the switches, S and S_2, to the controlling electromagnet on the starting signal.

Under normal conditions—*i.e.*, when the signal arm and the lever working it are both in the "on" position—the armature of the electromagnet on the signal is kept up to the poles, as shown in Fig. 63, and the continuity of the circuit is maintained in this position only. When the signal lever is put in the "off" position, this mechanical support is withdrawn, and if there is no current passing through the coils of the electromagnet the armature will fall, and the apparatus will occupy the position shown by Fig. 65. If, however, the local current through S, S_2, D has been previously established, the armature is held by the electromagnet, and the action of the balance weight on the levers and links allows the arm to assume

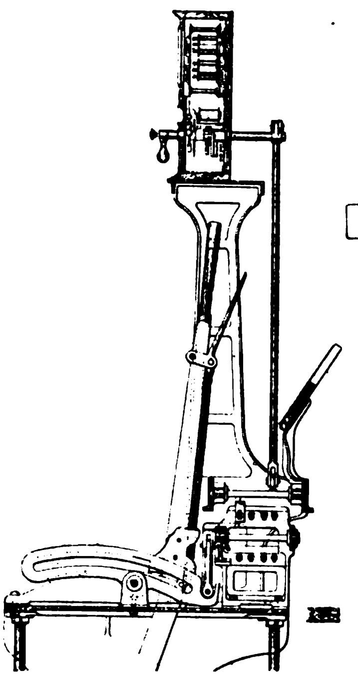

Fig. 62. – Interlocking of Bl ck Instruments with Point Fouling Running Line.

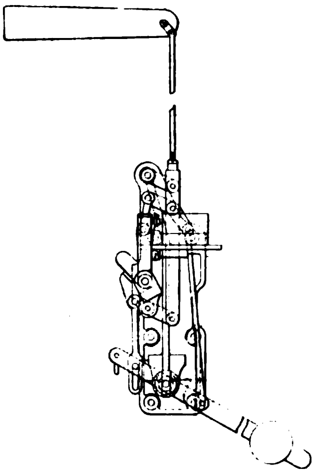

Fig. 63.

the "off" position as in Fig. 64. If a break occurs anywhere in the local circuit during the time the signal lever is "off," and the balance weight occupies the position shown in Fig. 64, the armature is freed, and, being unsupported mechanically, falls into the position shown in Fig. 65; the relative weights of the signal arm and the central lever carrying the rod being sufficient to effect this movement. An examination of the local circuit shows that it may be broken at three points—viz., at S, S_2, and at the signal. If the upper semaphore arm is raised, the switch S will break the local circuit. This action must take place when the signalman at the receiving end

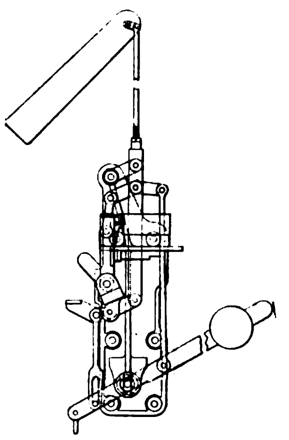

Fig. 64.

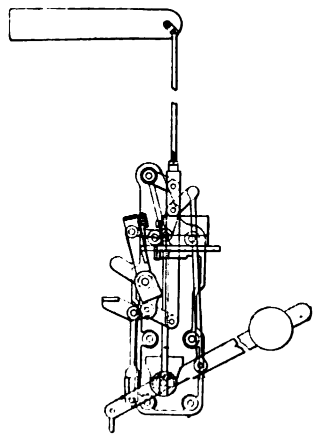

Fig. 65.

acknowledges the "Train on line" signal, and it therefore follows that the signal arm cannot remain at "off" after the "Train on line" signal has been acknowledged, although the lever working the arm has been left in the "off" position. Hence we see that the signalman at the sending end is not only dependent upon the signalman at the receiving end for the release of the starting signal, but the latter will replace it if the former neglects to do so. It is, however, by no means impossible for the signalman at the sending end to obtain the "Line clear" indication for a train and, from forgetfulness, neglect to forward the "Train on line" signal. Under such circumstances the signal

Digitized by Google

would remain at "off," if no other device than those described was in operation. A further examination of Fig. 66 will show that the electromagnet of S_2 is in connection with a second rail treadle, through the same battery as is used for the circuit S, S_2, and signal electromagnet. If this circuit is closed, the switch S_2 is reversed, and, breaking the circuit through the signal electromagnet, allows the arm to assume the "on" position. Although the closing of this circuit may be only momentary, it will be seen from Fig. 66 that the reversal of S_2 has the effect of diverting the current, previously passing through the signal electromagnet, through the electromagnet of S_2, and so maintains the reversed position of the latter until the indicating semaphore arm is raised, when, the switch S being open, the circuits from the battery, D, are broken, and S_2 resumes the position shown in the diagram of connections, and is ready for another train.

From the description it will be evident that the signalman at the receiving end is master of the situation. The signalman at the sending end cannot lower the signal for a train to proceed until he has received "Line clear" from the station ahead; and if he does not himself replace this signal at the proper time it is done by the acknowledgment of the "Train on line" signal from the receiving end; or, in the event of the train being sent forward without this signal being given and acknowledged, it is done by the action of the train passing over the treadle, and the signalman is unable to again lower it until the indicating semaphore has been raised and lowered again. When the "Train on line" signal is received from the sending end of the section, the signalman at the receiving end places the handle of his instrument in the midway position, which is the only movement possible, and acknowledges the signal in accordance with the code. The movement of the handle locks it in the midway position, and it cannot now be moved in either direction. The switch S_1 is closed by the same action. On the arrival of the train at the receiving end of the section, it passes over the treadle in connection with the battery, G, and a current is established through the switch S_1 and the handle-releasing coils. The armature is attracted, and allows L to drop into the position shown in Fig. 58. The handle of the instrument is now free, and may be placed in either the "Line blocked" or the "Line clear" positions. The proper position for it is, of course, the "Line blocked" position, and when this is done the "arrival" signal is given according to code.

This system is an interesting example of the possibilities of block working, and also of the difficulties to be overcome before even a moderate check can be established over those engaged on working traffic. The elaborate precautions taken to ensure the replacement of the starting signal after it has fulfilled its duty, and to ensure its not being used to send a train forward prematurely, mark the starting signal as being of the utmost importance in the estimation of the designer. There can be no doubt that the position of this signal is of great importance, but the history of railway accidents shows that its being in the "on" position has not always acted to prevent a train from passing into the section it protects, with disastrous results in some cases. The apparatus in connection with the starting signal has, obviously, been designed solely with the object of checking the action of the signalman, and provides in no way against the possibility of error on the part of that other important factor in the problem, the engine driver. Further consideration of the arrangements for unlocking the starting signal suggests the possibility of this being done through accidental contact between the line wire and another working wire along the route between the two ends of the section.

The next important point in the system is the locking of the instrument handle, at the receiving end, until the train has passed over the treadles in connection with the releasing coils. It will be noticed (Fig. 59) that the operation of locking commences when the instrument has been prepared to give the "Line is clear" signal, and is completed when the "Train on line" signal is acknowledged. Once the handle has been moved to the "Line clear" position it cannot, in the course of ordinary working, be replaced to "Line blocked" before the treadle is operated. An "Is line clear" signal or "Train on line" signal cannot therefore be cancelled, in the sense that all the apparatus concerned may be returned to the "Line blocked" condition without special arrangements being made for releasing the handle at the receiving end of the section. Theoretically, the "Train on line" signal should never require cancelling, but there are occasions when it may be necessary Cancelling of the "Line clear" signal is of much more frequent occurrence, more especially in connection with junction working and at points where traffic is lifted and left. In the case of a junction, such as is shown in Fig. 11, the signalman there might offer the "Is line clear" signal, and have it accepted, from two or even the three advance cabins, in which case the three starting signals would all be unlocked electrically, and any one of them might be used. Such a case as is here supposed is by no means far-fetched. Where signalmen at junctions have to deal with a heavy mixed traffic they often have to rely upon the whistles given by the driver, and when the wind is in a contrary direction it is by no means easy to distinguish the number and length of the whistles given; and since the "Line clear" signal must be obtained before the arrival of the train at the cabin at the sending end in order to prevent delay, the cancelling signal becomes of some importance. Further examination of the handle-locking mechanism shows that it is not impossible for the signalman at the receiving end to (*a*) replace the indicating semaphore arms to "Line blocked" in the interval between his giving the "Line is clear" signal and receiving the "Train on line" signal; (*b*) give the "arrival" signal to the sending end at any time after receiving and acknowledging the "Train on line" signal, but the locking of his instrument handle would prevent him from accepting a second "Is line clear" signal. The apparatus provides indications representing "Line clear," "Train on line," and "Line blocked" at the receiv-

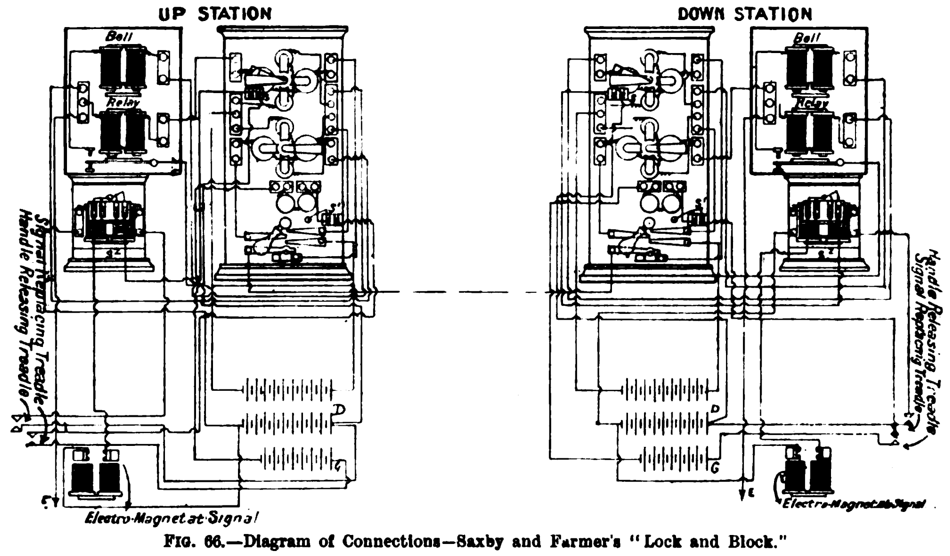

FIG. 66.—Diagram of Connections—Saxby and Farmer's "Lock and Block."

ing end of the section, but does not distinguish between "Line blocked" and "Train on line" at the sending end.

(To be continued.)

THE POSTMASTER-GENERAL'S REPORT.

The following extracts from the report of the Duke of Norfolk supplements in many ways the brief note we were able to give last week:

It is estimated that during the year ending March 31, 1896, the following postal packets were delivered in the United Kingdom:

	Number estimated.	Increase or decrease per cent.	Average number to each person.
Letters	1,834,200,000	Inc. 3·6	46·8
Postcards	314,500,000	Inc. 0·6	8·0
Book packets, circulars, and samples	672,300,000	Inc. 9·4	17·1
Newspapers	149,000,000	Dec. 1·8	3·8
Parcels	60,527,000	Inc. 5 9	1·5
Total	3,030,527,000	Inc. 4 2	77·2

Except in the case of newspapers, the figures show an increase upon those of last year and tend to justify the view of my predecessor that the apparent decrease in the number of letters in 1894 was not to be taken as denoting any real cessation in the growth of postal business. Looking back over a long period of years I find that this growth has been continuous, and I feel sure that it will be of interest to show in some detail the steps by which the primary business of the Post Office—that of carrying the correspondence of the country—has grown to its present dimensions. Into the early history of the letter post I do not propose to enter. It is a subject which has received and is still receiving much attention in my department; and I have been able during the past year to make arrangements whereby the voluminous archives of the Post Office, going back to the period of its first foundation, will be rendered more accessible to research. In the present report I have taken as my starting point the year before the establishment of uniform penny postage. In that year (1839) the number of letters (including six million "franks") which passed through the post was 82,000,000, and in the following year, under penny postage, it rose to 169 millions. At that time the newspaper post was already in existence, but no statistics of the number of newspapers carried are forthcoming. Up to 1855 newspapers were subject to a compulsory stamp duty which enabled them to pass free by post. From 1855 to 1870 they were not required to be stamped, but stamped newspapers passed free from other postage. Before 1870, however, other changes had been introduced into the postal service. In 1848 the book post was instituted at a rate of 6d. per pound, reduced in 1855 to 1d. for 4oz., and circulars were admitted to this post in 1856. The inland pattern post was established in 1863 at a rate of 3d. for 4oz, but this was reduced almost at once to 2d., and early in 1870 to 1d. for 4oz. Up to 1870 then, or during the first 30 years after the introduction of penny postage, the changes in the postal rates had not been extensive, but in 1870 changes greater than any which had occurred since the reform of 1839 were made. On October 1, 1870, postcards were introduced; the rate for book packets and samples was reduced to ½d. for 2oz.; and the rate for newspapers was fixed at ½d. irrespective of weight. In the following year the letter rate of postage, up to 12oz., was reduced to the present scale of 1d. for the first ounce, ½d. for the second ounce, and an additional ½d. for each additional 2oz. The sample post was abolished at the same time. The rates of postage for letters were not again altered till 1885, when postage on weights above 12oz. was reduced to ½d. for each additional 2oz. The book and newspaper rates have since remained unaltered, but a great stimulus was given to the book post in 1892, when greater freedom was given both in the mode of packing and in the definition of a book packet. To complete this summary of the changes of the conditions of the post it ought to be added that the price of postcards and the conditions of their use have been changed from to time since their first introduction in 1870. In 1872 a charge of ½d. a dozen in addition to the stamp was was made. In 1875 stout cards were first issued, and the charge for thin cards was raised to 1d. a dozen. In 1889 the present rates—viz., 1d. for 10 stout cards and ½d. for 10 thin cards—were fixed, and stout cards began to displace thin cards to the extent of 18 millions a year. On September 1, 1894, private cards first passed under a halfpenny adhesive stamp. Cards of "Court" size were issued on January 21, 1895. In consequence of these various changes, in 1894-95 the number of postcards of all sorts rose from 272 to 313 millions, while the number of official postcards showed a decrease of 31 millions. The number of letters and books have perhaps been slightly affected by the re-establishment of the sample post in 1887, and still more by the parcel post, established on August 1, 1883. The penny letter has long been known to be the sheet-anchor of the Post Office, and it is interesting to record that it appears, from returns taken last year, that no less than 95 per cent. of the total number of inland letters passed for a penny each. I am unable to state with certainty what proportion of the 315 millions of postcards delivered last year were official cards, but apparently they are now about half the total number. It will be observed that the total number of postcards has only increased by 0·6 per cent., as against 25·9 last year. This seems to show that the great impulse given to the use of postcards by the introduction of private cards has now spent its force. For the decrease in late years in the number of newspapers passing by post I am unable to account, but I presume that it is due to increased energy and improved system on the part of the great newsagents. From a revenue point of view the tendency to relieve the Post Office of the duty of distributing newspapers is no matter for regret, for, as has been often stated in public, the State loses much money by the work.

Parcel Post.—The number of parcels delivered in the United Kingdom during the year 1895-96 has increased by 5·9 per cent., from 57,136,000 to 60,527,000. The average postage per parcel is now 5·44d., of which the Post Office share is 2·86d. There has been no extension this year of the system of night mail coaches for the conveyance of parcels, but the total of parcels so conveyed has been largely increased. The total number of rail-borne parcels during the year was 52,196,217, an increase of 5·3 per cent. on last year, whereas the number of road-borne parcels was 8,331,221, an increase of 9 5 upon last year. The mild character of the winter enabled the coaches to maintain a regularity which compares favourably with the mail trains, and the mishaps were few and slight.

After referring to the acceleration of general mail services and to the express delivery of letters, the report deals with the money order and savings bank department.

Telegraphs and Telephones.—A very satisfactory increase took place in the number of both inland and foreign telegrams, an increase undoubtedly due to the revival of trade throughout the country. During the year 78,839,610 telegrams of all descriptions were forwarded, showing an increase over the previous year of 7,250,546, or 10·12 per cent.; 64,563,587 of these were ordinary inland telegrams—*i.e.*, excluding foreign, Press, and free telegrams—showing an increase of 5,656,179, or 9·6 per cent. The total revenue from inland telegrams was £2,046,456 as compared with £1,880,206 for the previous year, making the average revenue 7·61d. per telegram, as compared with 7·66d. The number of foreign telegrams dealt with by the Department reached 6,701,838, showing an increase of 764,123, or 12·86 per cent., as compared with the year 1894-95. This total does not represent the whole of the foreign telegraphic business of the United Kingdom. It only shows the number of foreign telegrams transmitted by the Post Office, and does not include those dealt with by the various cable companies without recourse to the postal telegraphs. 5,915,646 telegrams were transmitted at the Press rates for newspapers, clubs, etc., being an increase as compared with the previous year of 513,863, or 9·5 per cent. The average weekly number of words contained in these telegrams was about 13,650,000. Telegrams sent on behalf of the various Government departments show an increase of 22,722, or 8·33 per cent, the total for the year being 295,371, as compared with 272,649 for the previous year. The number of telegrams sent free of charge on behalf of the railway companies amounted to 1,338,818. This number represents an increase of 27·74 per cent. on the number, 1,048,064, sent in the previous year; but it is considerably below the numbers sent in former years before the arrangements for limitation of the number transmissible free of charge, to which reference was made in the reports for 1892-93, 1893 94, and 1894-95, came into operation. In continuation of these arrangements, a settlement has been arrived at with the Great Western and the Brecon and Merthyr Railway Companies for a limitation of their free message privilege, and there now only remain four companies with whom agreements have not been concluded. The numbers of the various kinds of telegrams as compared with the number in the previous year are given in the following table:

Class of telegram.	Number 1895-96.	Number 1894-95	Number Increase.	Receipts 1895-96	Receipts 1894-95	Receipts Increase
				£	£	£
Ordinary inland.	64,563,587	58,907,408	5,656,179	2,046,456	1,880,206	166,250
Press (inland)	5,915,646	5,401,783	513 863	124,881	119,061	5,820
Foreign.	6,701,838	5,937,715	764,123	331,717	286,215	45,502
Railway free ...	1,338,818	1,048,064	290,754	—	—	—
Railway half-rate	24,350	21,445	2,905	469	414	55
Government, free.....	295,371	272,649	22,722	—	—	—
Totals...	78,839,610	71,589,064	7,250,546	2,503,523	2,285,896	217,627

The London local telegrams show an increase of 644,921, or 10 14 per cent., the numbers for the year being 6,999,402 as compared with 6,354,481 in 1894-95.

New Cables.—The large increase in the number of telegrams passing over the Government cables to the Continent, and in the number of conversations on the telephone circuits between London and Paris, has rendered it necessary to consider the advisability

Digitized by Google

of improving the means of communication. With the cordial co-operation of the German Post Office, experiments were made with a view to improve the carrying capacity of the cables to Germany by the method of duplex working which has been employed with success on some of the Anglo-French cables; but, owing to the greater length of the Anglo-German cables, the results obtained were not sufficiently successful to justify the adoption of the system for practical working. Arrangements have now been made for the laying of three additional cables to the Continent—two to France, and one to Germany. These cables, each of which will contain four conductors, will afford a much-needed relief to the traffic, and it is expected that this new cable to Germany will prove suitable for duplex working.

Telephones.—The new agreement with the National Telephone Company, embodying the arrangement arrived at after prolonged and difficult negotiations extending over nearly four years, was executed on March 25 last. In accordance with the terms of the Treasury minute, on which the negotiations were based, the agreement restricts the operations of the company to local areas and places the trunk wires connecting those areas in the hands of the Post Office. Special facilities for using the telephone in connection with the telegraph and postal services are placed at the disposal of the public whether subscribers of the company or not. Thus, messages may be telephoned (1) for transmission over the postal telegraphs and delivery as telegrams; (2) for delivery as express letters; (3) for transmission and delivery as ordinary letters. The telephone may also be used for obtaining the services of Post Office express messengers. After considerable labour the experts appointed by the Post Office and the National Telephone Company to value the trunk wires of the company brought their work to a successful termination, the price agreed upon being £459,114. 3s. 7d. This amount was paid to the company on April 4 last. The length of trunk line taken over was 2,651 miles, and the length of wire about 29,000 miles. It has not yet been found practicable to transfer the working of the whole of these wires to the Post Office, as the special arrangements for leading in the wires, and fitting the necessary switchboards, etc., must necessarily occupy some time. The only wires the working of which has at present been transferred are those in the South of England. It is anticipated that the working of the whole of the remaining wires will be in the hands of the Post Office by the end of the summer. The telephonic service on the main system of trunk lines erected by the Department itself between the principal business centres of the United Kingdom to supplement those which it has now acquired from the National Telephone Company, was successfully inaugurated on June 12, 1895 On July 16, 1895, the system was thrown open to the public, and there has since been a steady development of the business. During the year additional telephone circuits between London and Bristol, London and Southampton, London, Lowestoft, and Yarmouth, and London and Guildford have been completed, while further circuits between London and Birmingham, Liverpool and Manchester, Manchester and Carlisle, and Newcastle and Carlisle are in course of construction.

Trunk Wire Charges.—The scale of charges for trunk line conversations of three minutes each has been revised. Under the scale laid down in the Treasury minute of May 23, 1892, the charges were as follows: for 20 miles or under, 3d; for 40 miles or under, 6d.; for every additional 40 miles or fraction thereof, 6d. Under the revised scale the charges are: for 25 miles or under, 3d.; for 50 miles or under, 6d.; for 75 miles or under, 9d.; for 100 miles or under, 1s.; for every additional 40 miles or fraction thereof, 6d.

Coast Communication.—Further progress has been made in the work of telegraphically connecting coastguard stations, etc., on exposed parts of the coast with the nearest lifeboat stations for the purpose of summoning assistance to vessels in distress; and I understand that the system has on several occasions been the means of saving life. Cables have also been laid to the Formby lightship and the pile lighthouse on the Maplin Sands. Some difficulty has been experienced in maintaining the cables which, on the recommendation of the Royal Commission, have been laid to some of the lightships. The cables become chafed and strained, and frequently break. Experiments are, however, about to be made with a view to establish communication with a lightship by means of induction, with a non-continuous cable, and it is hoped that these experiments will have a satisfactory result.

Profit on Post and Telegraph.—From the financial point of view the past year has been one of unexampled prosperity in the Post Office. The General Election and the revival of trade have combined to enable me to realise a profit of £3,632,122 Your lordships will, I doubt not, recognise in these figures a proof that my department continues to be administered upon the lines laid down by the Select Committee of the House of Commons in 1888, which dwelt upon "the necessity of working in the main upon business principles, and with a view to a profit on the transactions of each year," and added "that the high business character of the Post Office Department is no small degree due to the fact that it has been administered in this spirit and from this point of view.

BLACKPOOL CORPORATION ELECTRICITY SUPPLY.

We have received Mr. R. C. Quin's report as to the condition of the plant and system of working at Blackpool, together with suggestions as to modifications and improvements thereto. As the report is a long one, and in many cases enters into details not of interest to the general public, we have been obliged to condense it somewhat liberally. The report is addressed to the chairman and members of the Electric Lighting and Tramways Committee, and commences as follows:

Gentlemen,—Acting under your instructions I have carefully examined the state of the machinery and mains, and considered the present conditions of the supply both electrically and commercially. I would first remind you that I am not a partisan of either continuous or alternating systems of supply, believing that each case must be judged entirely on its own merits, and the system adopted which is most applicable to the particular town. Taking all the circumstances into consideration, it seems to me that the committee were well advised in adopting the high-pressure alternating supply. But I am not satisfied that the plant and machinery were the best that could have been used, nor that the class of mains, their method of laying, and the system of mains generally, were the best calculated to give a reliable and economical supply. In saying this I need hardly point out that I am not concerned as to the personality of the party or parties responsible for the blunders which have been made, but am dealing simply with the existing facts.

Buildings.—The committee are already aware of the state of the engine-room walls carrying the travelling crane, and of the necessity of a considerable expenditure to repair these and supply new girders for the traveller rails. The drainage is also in a very bad condition, due to the fact that there has hitherto been no suitable outlet, necessitating the drainage of the works to a low-level sump and the pumping from this to the higher level of the sewer. I have consulted with the borough surveyor on the subject, and he advises a connection being made to the new sewer in Bonny-street. This will obviate the necessity at present existing of running a steam pump for 24 hours daily.

Plant.—With regard to the engines and dynamos, none of these can be termed "highly efficient," the best set giving under 75 per cent. at full load, while the day set (No. 3) on half load (its usual output) gives only 35 per cent. efficiency. Only two of the engines can govern passably, the governors on the remaining engines being absolutely useless. When we consider the very large floor space occupied by this class of plant and the consequent large outlay needed for buildings, etc., together with their inefficient working, I am afraid the committee will regret their choice. I would not, however, recommend the replacing of this plant, seeing the very large amount of idle capital it would entail, but would suggest the provision of a new day set (a Parsons turbine) giving us something more than 35 per cent. efficiency, and the adoption of electrical governors for the remaining plant (excepting Nos. 7 and 8). The new 300 kilowatt Ferranti set now being installed has a guaranteed efficiency of 84 per cent.

Mains.—As I have previously said, the system of mains is not the best that could have been devised. There are five separate high-tension alternating circuits, the connections to the houses being either by transformers placed in boxes under the pavement or by transformers placed in the basements of houses. Very little distributing cable is employed. The disadvantages which this entails may be thus summarised: (1) No new premises can be connected without cutting off supply entirely from the circuit, which probably means leaving 70 or 80 customers without light during the time so occupied. (2) The continuity of the supply to a great number of customers depends entirely upon the maintenance in working order of one cable—a very risky proceeding, seeing their present state. (That Mr. Hesketh's opinion on this point is pretty much in accord with mine is proved by the following extract from his report of December 7, 1895, where on page 9, under the head of cables, he says: "Experience proves that it is not wise to have too great a load dependent upon any single cable.") (3) Generally speaking, every additional customer means increased current losses, since he must have a transformer, and current must be supplied to keep the transformer in working condition, whether the customer is using his light or not. The last condition even now means a considerable waste, for of the 35 per cent. obtained during the 20 hours of light load, from the day set, nearly 70 per cent. of this 35 per cent. is current needed to keep the numerous transformers in condition to supply current, and for which we get no return. Therefore the efficiency of supply during 20 hours of the day is only 11·5 per cent., and this allows nothing for steam-pipe and boiler losses—a very considerable item. This problem must at once be attacked, seeing that the transformer losses, under the present conditions, increase with the addition of customers.

Then as to the condition of the cables—upon the good working of each individual one of which so much depends—I find that the general rule in force here seems to have been to ram and jamb as many cables into one iron pipe as could be got by sheer force. At least that is the impression one gets from the results. In one 4in. pipe there are five high-pressure circuits (four of 2,000-volt alternating and one of 3,000-volt continuous)—that is to say, 10 single rubber insulated cables—how they were drawn in is a mystery to me. (As evidence of this see Mr. Hesketh's above-mentioned report, where on page 2 he says: "There are laid in the town 6 miles 650 yards of main piping, into which have been drawn 39 miles 1,350 yards of cable.") This gives an average of something over six cables per pipe. I have examined their condition, where they are visible at the draw boxes, and find the rubber in a great many places has perished. As sure as fate, if one cable breaks down the whole lot will follow suit. This is only one instance, but it is a fair sample of the state of affairs over

Digitized by Google

the whole town. The high-tension rubber cables have perished on all sides, and must be replaced by more lasting ones and different methods adopted of laying them. The arc lighting cables are similarly situated—that is to say, for practically their whole length they are drawn in the same pipes as high-pressure alternating cables. The condition of these arc cables is very bad—in fact, I do not think there is 100 yards out of the 11¼ miles laid which is worth more than its price as scrap copper. The repeated street-lighting failures are evidence of this deterioration. Of course, the breakdown of one cable in nine cases out of ten means the burning asunder of the other cables contained in the same pipe. Clearly, therefore, such a state of things cannot be allowed to exist. I attribute these failures to the action of the salt water; the pipes containing these cables being practically cisterns filled with muddy sea-water. The inter-chemical action between sea-water and iron pipes, and sea-water and rubber, and sulphates and chlorides, etc., of iron (formed by the action of the sea-water) upon the rubber readily account for its rapid deterioration. In my opinion neither rubber-covered cables nor iron pipes should have been used such circumstances, and I recommend their entire replacement by lead-covered cables laid in asphalte about 1ft. beneath the surface of the pavement [Note.—Since writing the above, I have been informed by Mr. William Chew, the assistant gas manager, and formerly your electrical engineer, that in the year 1879 or 1880 a similar breakdown was experienced. This was in the days of the first arc lighting of the promenade from the tall masts. Originally, the cables, which consisted partly of lapped rubber and partly of vulcanised rubber, were drawn in iron pipes. Within about 12 months of their being laid they had to be withdrawn from the pipes and suspended from posts, and when the new cables, having guttapercha insulation, were laid in wooden troughs filled with asphalte the trouble was overcome. It seems strange to me having had such an experience in 1880, the Electric Lighting Committee or their advisers should have committed the same error in 1893.] This is, in my opinion, the only method by which a sound and lasting main is to be obtained under the existing conditions. It is possible that the present alternating mains could be worked for, say, another six months, or at the outside 12 months, but this would place us in the very unsatisfactory position of continually expecting breakdowns and consequent stoppages of supply until the repairs were made. And not only would this result in a considerable loss of revenue, but public confidence in the reliability of our supply would be further shaken, and the replacement of electric light by gas would be brought about in numerous instances.

Transformer-Chambers.—With regard to the position of the transformers and the current losses entailed by their indiscriminate use, I propose to build, under refuges or pavements, in different parts of the town, transformer-chambers, each containing a number of transformers; the positions of these to be hereafter arranged with the borough surveyor. Each transformer chamber would be connected by a high-tension feeder direct from the works, and by inter-connecting cables to its neighbouring chambers. The supply to the houses would be by a network of low-tension cables completely connecting the transformer-chambers. By this arrangement we get an absolutely reliable supply, since it is independent of the good working of any one high tension cable, or of any transformer-chamber. As regards economy of working, it is obvious that, having the transformers completely under our control, we can suit their number and capacity to the demand, thus obtaining the most efficient conditions for working transformers. Further, we make the supply very much safer for the general public.

Plans and Estimates.—Plans showing the proposed rearrangements of the mains and positions of transformer-chambers have been made and are open to your inspection. I estimate the additional cost of modifying the high-tension mains to be £1,200, of low-tension mains £3,000, and of transformer-chambers £1,300, a total of £5,500.

Local Conditions Affecting Electrical Supply.—As the committee are very well aware, and as I need hardly point out, the conditions of the supply of electricity in Blackpool are very peculiar. For three months of the year the demand is equal to the capacity of the generating plant, but for the remaining nine months the maximum demand is less than half the summer demand. The yearly maximum is reached at the lightest season of the year, and therefore the length of time during which it is required is very short, whereas had this maximum been reached in winter the sale of electricity during that time would have been equal to three times as much.

System of Charging.—To encourage the winter demand the following new scale of charges is proposed: The charge for electricity consumed in the half-years ending June 30 and December 31 will be at the rate of 8d. per unit until the amount equals that required for a use of the consumers' demand for 182½ hours in the half-year—that is to say, for one hour per day on the average. All electricity consumed in excess of this quantity will be charged at the rate of 2d. per unit, provided always that the minimum charge for current to any consumer will be 10s. in any quarter. The consumer's demand will be taken to be the mean of the two monthly maximum rates at which electricity has been consumed in the months of April, May, and June of the first half-year, and July, August, and September of the second half year, and will be determined by the consumer's demand indicator. In order to prevent any single special demand for electricity raising the number of units chargeable at 8d., the consumer may, in the event of his intending to burn a number of lamps in excess of his usual maximum, on any such occasion (with the exception of the months of July, August, and September, and not exceeding once in each month) give 24 hours' notice in writing to the Corporation, and they will thereupon take steps to prevent the consumer's demand indicator from registering on the occasion so notified.' The cost necessary to carry out this reform in charging is comparatively very small, considering the large amount of capital affected by it. The cost of installing these maximum demand indicators works out at £700—that is, 1 5 per cent. on the capital at present invested, and as the whole aim of the system is to make such capital more productive, and as it strikes at the root of the difficulty, it must be admitted the expense of carrying it out is proportionately very little.

200-Volt Distribution.—It was not until recently that the Board of Trade, recognising the many advantages both from the consumers' and suppliers' point of view, and at the practically unanimous request of the electrical profession, consented to allow an alternating supply of electricity to be delivered to consumers at a pressure of 250 volts. The obvious advantages appertaining to such a system are the reduction of copper in the mains, the increased distance to which electricity can be transmitted with the same loss of power, the necessity for fewer transformer-chambers, and the reduction in the cost of meters, etc., inasmuch as by doubling the pressure we halve the current for the same power. The present condition in which we find ourselves, unfortunate though it is from many points of view, has at least one side a little less gloomy than the rest. I refer to the absence of any large sum of capital sunk in distribution at 100 volts, and the consequently comparatively small outlay now needed to adopt a higher pressure of supply, and thus reap the above-mentioned advantages. After carefully weighing the *pros* and *cons.*, I recommend that the pressure of supply be raised from 100 to 200 volts, and distributed on the two-wire system. This change of pressure will necessitate the replacing of the 100-volt lamps by lamps made for 200 volts, and I estimate that this will cost about £650. I would point out that the estimates for low-tension network, transformer-chambers, demand-indicators, etc., are based upon the assumption that the 200-volt distribution will be adopted. Should, however, it still be decided to distribute at 100 volts, and which I should very much regret, the above-mentioned estimates must be increased by 30 to 40 per cent. I would suggest that immediately after the meeting of the Council next following the decision of the committee, permission be obtained from the Board of Trade and public notice given of the proposed increase of pressure. That after the date of the expiration of such notice, all new consumers be supplied at 200 volts, and that steps be taken during the coming winter to place the whole supply on the basis of 200-volt distribution.

Supply to Tramways.—That there should be two entirely separate and distinct electricity generating stations within a town, owned and worked by the same body, one for power and the other for lighting, seems to be rather an anomaly. Moreover, it is by no means economical, entailing as it does the employment of two separate staffs for the one purpose. Further, as regards the lighting works, for the greater portion of the day the plant is practically idle, whereas it could be profitably utilised for working the trams. What I therefore suggest for the committee's consideration and sanction is the transference of the two Crompton dynamos from the tram-shed and their erection here coupled direct to a high-speed engine of approved type. The estimated cost of this inclusive of foundations, fixing, etc., is £500 Further, in view of the extension of the tramways now about to be carried out, I should deem it advisable to instal an additional 100 unit Parsons turbine combined with a continuous-current generator so arranged that it could supply either at 250 volts or 500 volts. The estimated cost of the latter is £1,100, and it would increase the electrical output of the tramways plant to more than double its present capacity. In addition to this there would be required a main connecting the electricity works to the tram-shed, and a further extension of the switchboard. These would cost about £200 and £250 respectively. No extensions of the present electric lighting buildings would, however, be necessary. Altogether, therefore, the further capital expenditure incurred by the suggested transference of the generating plant from the tram-shed to the electricity works would be about £2,050. The borrowing powers sanctioned for tramway purposes covers an amount larger than this, so that no application to the Local Government Board in this respect need be made. I have very carefully gone into the question of the cost of supplying current under such conditions from these works, and I have no hesitation whatever in saying that we can guarantee the maintenance of the necessary supply of current to the tramway department at 2½d. per unit, and at the same time leave us a satisfactory profit. Calculating the probable units to be sold to the tramways department at 130,000 per annum, this would effect a saving in their revenue account to the extent of £270 upon the year's working, and leave us a profit of about £500. In other words, the saving to the Corporation annually would be at least £700 if taken on the basis of the present cost of generation. In this connection it will be remembered that the estimated output last year was 128,174 units, so that with the extensions before named it is quite probable that the demand will be considerably over 130,000 units per annum, in which event the saving will increase *pro rata*.

Conclusions.—Annexed hereto (Appendix B) I give a statement of the expenditure of capital—apart from that necessitated by the replacement of the present rubber cables by special lead-covered ones—which I estimate will be involved by the alterations I have sketched out. In conclusion, I cannot too strongly impress upon the committee my sense of the hopelessness of the future prosperity of these works unless some immediate steps are taken to remedy the defects I have already indicated. It is not a question of saddling, or attempting to saddle, the responsibility of past errors

Digitized by Google

upon the shoulders of any individual or individuals. It is emphatically rather a question of repairing the errors before they become irreparable. Towards the accomplishment of this object I have given much careful and anxious thought; and the proposals, suggestions, and recommendations I have embodied in the foregoing report will, I firmly believe, if carried out in their entirety, bring the electrical portion of the works up to a high level of excellence, and place the financial future of the undertaking beyond the possibility of failure.

The main points of my report to which I beg to draw my committee's most especial attention are: (1) The replacement of faulty mains; (2) the increase of the pressure of supply; (3) the adoption of demand indicators; and (4) the transference of the tramways supply to the electricity works from the present tram-shed. By these means there will be brought about, in my opinion, the absolute reliability of the supply, the economical working of the plant, the minimising of the financial risk, and, generally, a great saving to the Corporation by the fuller utilisation of the resources of the electricity works. I feel I should have failed in my duty had I not most fully put the case before the committee, and, without blinking any facts, gone to the root of the trouble, and shown exactly what it is and how it can be remedied. It is now for the committee to say whether this report is worthy of their acceptance, and whether the electricity works are ultimately to become a success or a failure.

APPENDIX B.—Statement of Unspent Balance of Capital last sanctioned by Local Government Board and the manner in which it is proposed to be diverted.

Balance of Capital Unspent.

Foundations	£80
Boilers, condensers, etc.	2,321
Alternator	3,843
Rectifier	413
Cables and pipes	2,707
Transformers and meters	7
Public lighting	1,556
Coal bunkers, test-room, stores, tools, and general expenses	1,038
	11,965
Less amount overspent on steam-pipes, etc., £226, and switchboard and instruments, £50	276
Approximate total	£11,689

Proposed Diversion.

New drainage scheme, as per borough surveyor's plans and estimates	£400
Covering of boilers and steam-pipes	100
One new 50-kilowatt Parsons turbo-alternator	650
Three new electrical governors fitted complete at, say, £50 each	150
Additional high-tension mains for the inter-connection of the present system along Dickson-road; from works to Church-street *viâ* Coronation-street; from works to Park-road; along Station-road and Alexandra-road, laid complete, say	1,200
Low-tension cable along Promenade, Lytham-road, Waterloo road, Station-road, Victoria street, Church-street (part), Dickson-road, Park-road, Albert-road, and Coronation street respectively, laid complete, say	3,000
New services to, say, 100 consumers, at £10 each complete	1,000
Nine transformer-chambers, fitted complete, say	1,300
Public lighting, provision of 50 arc lamps	800
New coal bunkers, test-room, stores, and general expenses	1,040
Demand indicators, fitted	750
200-volt lamps for increased supply pressure	650
Contingencies, say	649
Approximate total	£11,689

COMPANIES' MEETINGS AND REPORTS.

SUSSMANN ELECTRIC MINERS' LAMP COMPANY, LIMITED.

The statutory meeting of this Company was held on Monday at the Cannon-street Hotel, E C., the Earl of Westmorland presiding.

There was no resolution for the meeting, but the **Chairman** made a brief statement as to the progress of the Company during the last four months. The directors were in negotiation with Belgium, South Africa, and France with regard to the sale of their foreign patents and were shipping sample lamps to India. Many enquiries had been received from different collieries both in England and Wales. The lamp was absolutely the best lamp yet invented for underground work. The Edison and Swan Company, with whom the Board had arranged for the making of the Süssmann lamp, would be in a position to start the manufacture almost at once.

The proceedings occupied only a very few minutes.

West India and Panama Telegraph Company.—For the half-month ended August 31 the receipts were £1,660, against £1,617 for the corresponding period of 1895.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Rome.—Tenders are wanted by September 9 for the supply of 70 000 battery zincs for the Italian Ministry of Posts and Telegraphs.

Ardenne (Belgium).—Tenders are wanted by September 8 for the electric lighting of the town Application to the Hôtel de Ville, Ardenne (Namur).

Paris.—Tenders are wanted by September 8 for the supply of magneto-electric calls for the Departments of Posts and Telegraphs, rue de Grenelle 103, Paris.

Spa (Belgium) —The Burgomaster and Echevins of Spa invite propositions for undertaking the public lighting, either electrically or by acetylene. The date fixed is September 15. No further information is given in the official advertisement.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Brussels.—La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Odessa.—The Municipal Authorities have decided to offer for tender the electric lighting of part of the suburbs and the new prison. No date is given, and application must be made to the Municipal Delegation at Odessa, but certain particulars can be obtained at the Ministry of Commerce (bureau de renseignments commerciaux), Paris, rue de Varenne 80.

Amsterdam.—Up to September 12 the Consul-General of the South African Republic (Transvaal) will receive tenders for the supply of insulators with supports. The address is at Doelenstraat 8, Amsterdam. Specifications will be procured on demand by Mr. F. J. Belinfante, late A. D. Schinkel, Paveljoensgracht, The Hague, at the price of 1sh.

Brussels.—Tenders in connection with the construction of an acetylene generating station at Forest, for La Société anonyme, bruxelloise pour l'exploitation de l'acetyléne pour Raoul Pictet will be received on September 5 (later tenders disregarded). There are six contracts for the different species of work. Application for particulars is to La Société, etc., Brussels, rue Royale 121.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Oldham.—The Electric Light Committee invite tenders for the various works required in the extension and alterations of the buildings of the electric light station in Gas-street, Oldham. Specifications and drawings can be seen. and schedules of quantities obtained, on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham. A charge of £1. 1s. will be made for the schedule of quantities, which will be returned on receipt of a bona fide tender. Tenders to be sent in by September 15.

Blackpool.—The Corporation are prepared to receive tenders for the supply, laying, and maintenance of high-tension and low-tension lead-covered cables and the supply of all necessary jointing sundries. Specifications and bills of quantities, together with forms of tender, may be obtained from the Borough Electrical Engineer, on payment of 10s. 6d, which will be returned on receipt of a bona fide tender. Tenders, addressed to the Chairman of the Electric Lighting and Tramways Committee, and endorsed "Tender for Cable," should reach the offices of Mr. Robt. C. Quin, borough electrical engineer, Corporation Electricity Works, Blackpool, not later than September 8.

Digitized by Google

Hull.—Pending the decision of the Town Council as to the leasing of the tramways or the working of them by the Corporation, tenders are invited for a license to temporarily work and use the tramways for one year from October 15, 1896, upon the terms and conditions embodied in the draft of an agreement, which can be obtained by application to Mr. R. Hill Dawe, town clerk, Town Hall, Hull. Tenders, stating the amount of rent offered, must be delivered at the Town Clerk's Office, by 10 a.m. on September 21, in sealed envelopes, endorsed "Tender for Temporary Working of Tramways."

Cadiz.—The Secretary of State for Foreign Affairs has received dispatches from her Majesty's Consul at Cadiz, stating that preliminary tenders for a supply of electric lighting apparatus for the illumination, on the most approved modern plan, of private houses, etc., in the town of Cadiz are invited by the "Sociedad Co-operativa Gaditana de Fabricacion de Gas." It appears that the tenders should be sent in by September 15 to the above-named company, whose offices are San José, 25, 27, and 29, Cadiz. Firms wishing to obtain the contract for the supply of plant are advised by the Consul to send representatives to treat personally with the company. Such additional particulars as have reached her Majesty's Government on the subject may be viewed at the Commercial Department of the Foreign Office, any day between the hours of 11 a.m. and 6 p.m.

Cork.—The Mayor, Aldermen, and Burgesses of the city or borough of Cork invite tenders from persons or companies willing to carry into effect the powers conferred upon the Corporation of Cork by the electric light provisional order of 1896. The Corporation of Cork have made arrangements with a tramway company, who propose installing an electric tramway system in Cork, whereby the supply of current for the tramways must be taken by the tramway company from the assignees of the electric light provisional order, and the advantages of this arrangement are specially pointed out to the intending tenderers. A copy of the conditions under which the order may be transferred, and form of tender, prepared by Messrs. Kincaid, Waller, and Manville, may be obtained from Mr. Alexander M'Carthy, town clerk, Municipal Buildings, Cork, on payment of £1. 1s., which sum will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Application for Transfer of Electric Light Provisional Order," to be sent by 12 noon on September 11 to the Town Clerk.

RESULTS OF TENDERS.

Estepa (Seville).—The electric lighting contract for this place has gone to the Faro de San Vincente Company at 7,500 pesetas annually for 10 years.

Paris.—For the limited competition for armoured cables, etc., in the avenue de l'Opera, the contract has gone to the Société industrielle des téléphones.

Altona.—The accepted tender for the supply of a 12-ton electric crane for the Prussian State Railways at Altona on August 17 was that of Carl Schenck, Darmstadt, at 7,450 marks (about £372. 10s.).

Cassel.—For the contract for 80 incandescent lamps and 14 arc lamps for the municipal authorities the lowest tender was that of the Allgemeinen Elektricitätswerke, Hanover, at 5,465 marks. There were eight tenders in all.

The Hague.—For the supply to the Dutch Colonial Ministry of 2,700 iron telegraph posts on August 26 the lowest tenders were those of the Prins van Oranje Ironworks at The Hague. For galvanised iron wire, insulator pins, etc., the lowest tender was from Messrs. R. S. Stokvis and Son, Rotterdam.

Islington (London).—The tenders for the enlargement of the central electric lighting station, Eden-grove, Holloway-road, N., for the Vestry of St. Mary, Islington (Mr. A. Hessell Tiltman, F.R.I.B.A., 6, John-street, Bedford-row, W.C., architect), were as follows:

G. Sharpe, Gilbens-road, Stratford, (accepted)	£7,540
Munday and Son, Catherine House, Trinity-square, Tower-hill	7,690
Thompson and Beveridge, 191, Euston-square, N.W.	7,940
Leslie and Co., Limited, St. James House, Kensington-square	8,015

BUSINESS NOTES.

Holywell (Wales).—The new line of telegraph from Holywell to Halkin has been opened for the transmission of telegraphic messages.

Epsom.—The Urban District Council have appointed Mr. W. C. C. Hawtayne, of 20, Bucklersbury, E.C., as consulting electrical engineer.

Londonderry.—Mr. Christie, electrical engineer, has presented his report to the Lighting Committee. It dealt mainly with the rearrangement of certain lamps, and was duly adopted.

New Address.—In future the offices of the Brockie-Pell Arc Lamp Company, Limited, will be at 97, Queen Victoria-street, E.C., to which address all communications should be sent.

Western and Brazilian Telegraph Company.—The receipts for the week ending August 28, after deducting 17 per cent., payable to the London Platino-Brazilian Telegraph Company, were £2,791.

Tiverton (Devon).—A promenade concert and exhibition of electrical appliances has been held at Broomfield, the residence of Major Gardner, in aid of the funds of the Tiverton Infirmary and Dispensary.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending August 30 amounted to £1,300, as compared with £1,272 in the corresponding week of the previous year, being an increase of £28.

St. Pancras (London).—The Vestry have sealed an agreement with Messrs. Shoolbred and Co., of Tottenham Court-road, in regard to the laying of two pipes under that thoroughfare, between Nos. 116 and 154, for the conveyance of electric lighting wires.

Blackpool.—Mr. R. C. Quin's report on the position of matters at the town electricity works has been adopted by the Town Council, and the considerable alterations and extensions recommended are to be carried out. Mr. Quin's report is given in full elsewhere in our columns.

The City Polytechnic.—We have to note the receipt from the City of London College, White-street, Moorfields, E.C., of the syllabus of lectures in the engineering department under the guidance of Mr. H. Adams, M.I.C.E. The college calendar will not be obtainable till October.

City and South London Railway.—The returns for the week ended August 30 were £835, compared with £786 for the corresponding period of last year, being an increase of £49. The total receipts for the half-year 1896 were £8,333, compared with £7,669 last year, being an increase of £664.

Taunton.—The Lighting Committee have decided to continue the arc lamps along the upper end of Calverley-road, and place one in Monson-road, making four in all. These are to be alternating-current arcs, and if they are found satisfactory no more rectifiers will be put down at the generating works.

Automobiles.—Messrs. Whittaker and Co. are about to issue an authorised translation of Mr. D. Farman's recent and well-known work upon "Automobiles." It will be fully illustrated, and contain constructional details of the latest work. The translation has been carefully done by Mr Lucien Serraillier.

Bridlington.—The attention of the Highway Committee of the District Council having been drawn by Mr. W. C. Townsend to the erection of telephone wires by the Telephone Company and private users from their houses to business premises, a committee has been asked to report as to the powers of the Council in such cases.

South Shields.—There was little ceremony at the inauguration of the electricity works on Tuesday. The current was switched on by the Mayor, and an adjournment was afterwards made to the town hall, where a few speeches took place, and the healths of the Electric Lighting Committee, the engineer, and contractors were proposed and responded to.

Aluminium.—The British Aluminium Company having started the production of aluminium at their works at Foyers, according to *Aluminium and Electrolysis*, the quality has been found to be exceptionally good, and compares very favourably with the foreign metal hitherto sold. The company are now the only manufacturers of the metal in the United Kingdom.

Windermere.—Subject to the approval of the Highway Committee, the District Council have agreed to seal a contract with Messrs. R. H. Fell and Son for the electric lighting, the Council to pay £1. 6s. 9d. per lamp per 1,000 hours, including the cost of the incandescent lamps, but excluding that of the globes and fittings, which would cost £1. 18s. per set.

Dover.—The use of motorcarts in connection with street scavenging has been under discussion by the Town Council, and it was decided to delay, pending further information on the subject, the erection of extensive stabling accommodation on land the Council have purchased for a scavenging depot. The borough surveyor will report on the tramways scheme in a fortnight.

Coatbridge (Lanark).—At a special meeting of the Town Council it was reported that the Scottish House-to-House Electricity Company had declined to light the arc electric lamps in the streets at 15s. per lamp, and the Council remitted the matter to the Lighting Committee, with powers to come to the best arrangement possible with the company so as to have the lamps lit.

New Company.—The Northern Electrical Engineering and Plating Company, Limited, has been registered, with a capital of £1,000 in £1 shares, to carry on the business of electrical and general engineers, electroplaters, shipbuilders, machinists, fitters, founders, millwrights, smiths, wire-drawers, metallurgists, and metal merchants. The office is at Brewery-lane, South Shields.

Exeter.—The electric light company has been summoned before the local magistrates for the non-payment of £3. 18s. 0½d. poor rate. The demand note was served on the secretary to the company, but it appeared that the summons was served on Mr. Knill, who is a receiver on behalf of the debenture-holders, and not an official of the company. The result of this was that the Bench dismissed the case.

Douglas (Isle of Man).—The opening of the Upper Douglas Cable Tramway, which has been promoted by the Isle of Man Tramways and Electric Power Company, Limited, to deal with the traffic from the Victoria Pier, Douglas, to the north end of the town, was celebrated by a public demonstration. The reason of the adoption of cable rather than electric traction on this piece of line is the extreme severity of the gradient.

Digitized by Google

Cork.—The premises at the "Wonderland" Bazaar will be lighted throughout by electricity. Messrs. Handley and Shanks, 33, Patrick-street, Cork, have been entrusted with the work. The total number of lamps will be over 300. For outdoor illumination six 2,000-c.p. arc lamps will be used The plant necessary for producing the current required will consist of one steam-engine, 30 i h.p., two gas-engines and three dynamos.

Havre (France).—Messrs Lazare, Weiller, et Cie. have just started at Hâvre important works for the manufacture of copper, bronze, steel and iron wire, and French wire nails, and their English agent, Mr. F. Espir, informs us that they are ready to enter into contracts for delivery after October 1 next. The motive power of the new works, which is equal to more than 3 000 h.p., is entirely distributed by electricity, and there are about 120 motors employed in the different shops.

Bolton.—At the meeting of the Gas and Electricity Committee, the electrical engineer has reported that the cable for the supply of electricity in Bromwich-street, Haulgh, would be commenced immediately. He also reported an application for a supply of electricity at the Park Sawmills, Spa-road, and it was agreed to lay the requisite mains subject to the number of lamps taken being satisfactory. It was decided to purchase an incandescent street-lighting apparatus as a test.

Northwich.—The Urban District Council have sealed an agreement with the newly formed Northwich Electric Supply Company, who have applied to the Board of Trade for powers to supply electric light in the rural and urban districts. The principal clause in the agreement gives the Council the option of purchasing the concern at the end of 14 years on repayment of expenditure incurred in buildings and plant and the payment of 7½ per cent. for any year when a less dividend has been declared.

Catalogue.—We have received from Messrs. John Davis and Son, of All Saints' Works, Derby, their catalogue of mining, surveying, engineering, and mathematical instruments. It may be noted that Messrs. Davis and Son state that further experience in the use of aluminium has confirmed their opinion that that metal properly alloyed is invaluable for surveying instruments. In the catalogue the principal instruments and apparatus have attached a cable-code word for the convenience of foreign orders.

Kingston-on-Thames.—The electric lighting capital account, as presented to the Town Council, shows that loans amounting to £23,772 have been raised, of which £7,722 has been lent during the past year. The capital expenditure has been as follows: for buildings, £4,279. 9s. 5d.; machinery, £11,180. 15s. 8d.; mains, etc.. £6 748. 19s. 3d.; transformers, £630; meters, £667. 14s. 4d.; electrical instruments, £86. 0s. 5d.; sundries, £268. 14s. 1d.; which, with the cost of loans, etc., £114. 15s. 8d., makes a total of £23,974 8s. 10d.

Appointments Vacant.—The Council of King's College, London, are open to receive applications for the post of demonstrator of mechanical engineering. Particulars can be obtained on application to the Secretary.—A head master is wanted for the Banbury Technical School, but science and technology do not appear to be the most important qualifications. Application may be made to Mr. Whitehorn, Municipal School, Banbury.—The Blackburn Corporation want an assistant electrical engineer at £125 a year. Application is to the Town Clerk

Tunbridge Wells.—At the Town Council, in moving the adoption of the report of the Lighting Committee, Mr. Ashby Wood was asked some questions. Mr. Gower desired to know whether the new system of lighting already paid or was a loss to the borough? Mr. Wood replied that, although a year had not yet passed, the proceeds of the new electric light paid the sinking fund and the rate of interest if there was no profit as yet. Therefore, the town was to be congratulated, seeing that in some towns they had a loss on the new works for several years. There had been great progress in the adoption of electricity by all classes for houses and shops, and he hoped that they would soon see a profit for the Corporation.

Fresnes-les-Rungis (France).—Further particulars have been published as to the competition for schemes for lighting the prisons at Fresnes-les-Rungis, in the Department of the Seine. A complete installation is required for 2,500 10-c.p. and 600 16 c.p. incandescent lamps and 50 10-ampere arc lamps, with provision for a possible addition of 500 extra incandescent lamps in the future. The boilers must also provide power and heating for the laundry, baths, etc. Either an alternating or a continuous current plant is admissible, but provision must be made for running in parallel, and the distribution must be on the three-wire system at 110 volts between the exterior and neutral wires. The estimate for the work is put at 254,305fr. as a maximum, which must not be exceeded.

Failure.—The first meeting of the creditors of Paterson and Cooper has been held. The debtors were electrical engineers, carrying on business at Prince's-mansions, Victoria-street, and Dalston, and also at Glasgow. The receiving order was recently made, and a special manager was appointed with a view to the completion of certain contracts. The statutory accounts were not filed, but the Official Receiver said that, from figures furnished to him by the debtors, and which must be accepted with reserve, it appeared that the unsecured indebtedness was estimated at about £11,000, and the assets at £18,000, in addition to interests in certain patents. The debtors made no proposal, and a resolution for bankruptcy was passed. Mr. Edward Moore, accountant, was appointed trustee of the estate, together with a committee of inspection.

Electrical Undertakings.—Under the title of a "Manual of Electrical Undertakings," a new annual is to be issued in October next by Messrs P. S. King and Son, King-street, Westminster. The annual will be compiled under the direction of Mr. Emile Garcke, M.I.E.E., chairman of the Electrical Section of the London Chamber of Commerce, and will contain particulars of the last published accounts of established electricity supply and electric traction undertakings, whether owned by companies or by municipal corporations, and of telegraph, telephone, manufacturing, and other electrical companies; and also particulars of all electrical companies registered since 1856, the year of the first Joint-Stock Companies Act, as well as the names, arranged alphabetically, of the directors and other officials of the various electrical undertakings.

Madagascar.—The Madagascar papers have contained a statement that Mr. Laroche, the French Resident-General, had granted to a Mr. de Coriolis, described as a former member of the House of Commons—he is really a member of the Mauritius Legislative Council—a concession for the construction of railways in the island, and to establish electric lighting works. The Paris *Temps*, commenting on this report, says: "It is true that Mr. de Coriolis has made proposals to Mr. Laroche, in the name of the British company of which he is the representative, and that the Resident-General has taken notice of the request by intimating to Mr. de Coriolis that he will transmit the proposals to the French Government. Mr. de Coriolis made a mistake as to the meaning of this reply. His proposals, which have been communicated to the Ministry of the Colonies, will result in nothing."

Brighouse.—The sub-committee appointed with regard to the purchase of the electric lighting plant from Mr. A. B. Brook have presented their report to the Town Council. The sub-committee state that they have had the plant valued by Mr. Blakey, of Bradford, and they have made Mr. Brook an offer of £1,535 for the plant, which has been accepted, and they recommend that the plant be purchased for this amount, Mr. Brook to work the plant at his own risk till the license to supply electricity has been obtained by the Corporation from the Board of Trade, and that afterwards the Corporation take over the plant and pay Mr. Brook £100 per annum for the use of the overhead wires till such time as the Corporation can lay them underground; but the committee are advised that the Board of Trade will not allow these wires to be used for more than two years after the license is granted. The report was adopted.

Accrington.—To the Accrington and Church Co-operative Society belongs the credit of laying the first installation of electric lighting in Accrington. The central stores of the society would in all probability have been lighted by electricity 12 months ago but the Board delayed matters in anticipation of an electric lighting plant being put down by the Corporation. This, however, did not come about and the society resolved upon providing its own current. The installation is for about 425 incandescent lights in the various shops and rooms, and in addition there are six arc lamps, two in the central grocery department and four in the drapery establishment. Willans-Crompton direct-coupled engines and dynamos are used and there is an Epstein accumulator. The contractors for the work are the Nelson Electrical Engineering Company, and the work has been carried out under the supervision of Messrs. J. McLellan and Co., of Blackburn, as consulting engineers.

Knutsford.—At the meeting of the Bucklow Rural District Council the clerk read a letter from Messrs. Brett, Hamilton, and Tarbolton, solicitors, Manchester, on behalf of the Carriage and Tramways Company, who propose to extend their system of tramways through Stretford, Sale, Tarporley, Altrincham, Dunham Bowdon, and Peel Causeway, and work them by electric or other mechanical traction; and it was resolved to ask the promoters to attend a meeting of the Council with plans. Mr. Sampson, solicitor, and Mr. Andrew attended the Council with reference to scheme of an electric tramway from Peel Causeway to Stockport, taking a route through Altrincham, Timperley, Sale, Stretford, Old Trafford, Moss Side, Withington, Longsight, Levenshulme, Heaton Norris, to Stockport. It was stated that the tramway would be worked in connection with the present system of electric lighting either by the same company or by arrangement for supplying power. Mr. Andrew explained the scheme, stating that it was simply an extension of the Manchester tramways to Peel Causeway, and nearly encircling the whole of Manchester and its suburbs.

Pekin.—According to the *Scientific American*, the "Pekin University," an educational institution conducted by the American Methodist Episcopal Mission, has recently opened in one of its buildings a museum which it is proposed to devote largely to the exhibition of foreign machinery and mechanical appliances. This museum is visited daily by increasing numbers of the people of the better classes, and the authorities would be glad to receive and exhibit models and drawings of electric or any other machinery. Each exhibit which may be presented to them will be marked in Chinese, with the name and address of the maker, together with the description and price, if desired, and a capable translator will explain their use to enquirers. Correspondence on this subject and articles for exhibition may be sent to the Pekin University, Pekin, China; or to Mr. Charles H. Taft, treasurer, 78, William-street, New York, U.S.A.; and under an arrangement with the Chinese Customs Department any exhibits will be imported into China free of duty.

Belfast.—At the meeting of the Electric Committee the assistant engineer, Mr. Olsson, attended, and reported on the application made on behalf of Messrs. W. and G. Baird for a reduced rate for

Digitized by Google

a large supply of electric current for driving printing machines, and it was decided to recommend the Town Council to authorise a special scale for this and all similar cases of large daylight consumption. At the monthly meeting of the Corporation the Lighting Committee's report, which was adopted, contained the following: "Your committee have to report that the arbitration with Messrs. M'Comish and Shaw in regard to the light in their premises, which was obstructed by the buildings of the central station, resulted in an award of £48 to be paid by the Council. In order to encourage the daylight consumption of current, and to meet the requirements of the different industries likely to adopt electric motors for daylight use, your committee recommended that they be authorised to supply current at the specially reduced rate of 2¾d. per unit for all current used over 4,000 units. Your committee have to report that it is now necessary to provide the additional plant referred to in previous reports, and they are in treaty for the supply of one additional direct-driven engine and dynamo."

Leeds.—We mentioned last week that the Tramways Committee of the Leeds Corporation selected for consideration the names of five out of a total of 35 applicants for the position of clerk of the works in respect of the projected electric tramway from Roundhay Park to Kirkstall. The committee have now had all five applicants before them, and finally decided by a narrow majority to recommend the appointment of Mr. John Burbridge, the manager for the Thomson-Houston Company of the late electric tramway on Roundhay-road. The candidates were Mr. F. B. Lea, of London; Mr. Ernest K. Scott, of Wolverhampton; Mr. C. F. F. Smith, of Blackpool; and Mr. H. G. Sprague, of London. Each one was requested to mention the amount of salary he hoped to receive, and the sums named varied from £2. 5s. to £5. 15s. per week. Mr. Burbridge asked the sum of £3. 3s. An amount much in excess of this was asked by Mr. Ernest Scott, and his qualifications so impressed the committee that he nearly secured election. In selecting Mr. Burbridge the committee were influenced to a considerable extent by his experience on the old Roundhay electric tramway. The appointment was afterwards confirmed by the full Highways Committee, and will be submitted to the full Council for approval. The committee intend to push on with the new tramway as rapidly as possible.

Leith (Midlothian).—On the discussion in the Town Council of a motion "that the magistrates and Council resolve to apply to the Board of Trade for a provisional order authorising them to supply electricity for public and private purposes within the burgh," Bailie Manclark, who moved the resolution, said that the burgh would probably have been better off if they had gone in for electric lighting a year or two before, because those who had the power were now making the light for themselves, and the Corporation had thus lost their custom. Another reason was that they would not have had the taunt of Edinburgh offering as a reason for amalgamation that they would have the electric light. The committee had gone thoroughly into the matter, and he stated that the approximate cost would be £25,000. They anticipated that there would be considerable saving to the baths in having the electric light station near it. They estimated the annual expenditure on the working of the plant as £2,780, and the revenue as £6,850, leaving a probable balance of £4,070 if the whole plant was thoroughly occupied, and of £133. 10s. if only half the plant was put on. Moreover, electricity might be used for the tramcars. Councillor Craig seconded the resolution. He thought the people of Leith wanted the light. Councillor Baxter feared that they would never be able to produce the light as cheaply as in Edinburgh. Ultimately the motion was agreed to, and it was remitted to the Electric Lighting Committee to take all necessary steps and submit to the Council a draft of the proposed order.

Liverpool.—In the Town Council Mr. Richard Dart moved the recommendations of the Lighting Committee for reducing the price of current—namely: "That meter rents be reduced from 2s. to 1s. per month; that in the place of the present uniform charge for electrical energy of 7½d. per unit the following scale be adopted: for each unit up to 1,000 units per month, 7d. per unit; for each unit in excess of 1,000 units per month, 4d. per unit; that the charge for electrical energy for heating, cooking, or power (when supplied through a separate meter) be reduced from 5d. to 4d. per unit; that consumers occupying two or more places of business be allowed to have them included in the same account; that the above reductions come into force on October 1, and be subjected to the general conditions of supply and installation regulations of the Corporation electricity supply department." Mr. Dart explained that the committee wished to move slowly. In the cases of large consumers, however, they were making a great reduction, because it was obvious that these consumers might erect works for themselves, and they were entitled to have their work done cheaply. The committee were fully alive to the importance of pushing forward the lighting of the city. Mr. G. H. Ball asked whether the committee had calculated upon making sufficient profit to leave a margin upon the working of the undertaking, or were they going to act in a spirit of philanthropy. Mr. Dart replied that the committee would not feel themselves at liberty to reduce the charge beyond a paying point unless they distinctly informed the Council of the fact. Mr Rutherford said he had been informed on excellent authority that the electric light could be supplied much more cheaply—35 or 40 per cent. more cheaply—by the high-pressure system than by the low pressure method. It would also do away with the necessity for the numerous stations which were costing so much money. He wished to know whether the committee were taking any steps to ascertain the comparative cost of producing electricity. Mr. Dart said he learned from the electrical engineer that the cost of the electricity by the high-pressure system was not much smaller than by the other method. Moreover, the high-pressure system was most dangerous, and he should be loth to see it introduced into Liverpool. The recommendations were then confirmed.

Morley.—Public notice has been given by the Corporation of their having obtained from the Board of Trade an electric supply license, and a beginning of the work was made last week, when a gang of men were started laying pipes underneath the footpath in the main streets for the electric lighting cable. The scheme has been prepared by and is being carried out under the supervision of Mr. Robert Hammond, London. So far back as 1893 the Town Council began to seriously consider the question of electric lighting, and in August in that year the Electric Lighting Committee advertised for schemes for the electric lighting of the town hall and the borough generally, and offered a premium of £100 for the scheme which was considered most suitable. The result was that nine schemes were received, and, after consideration, that from Mr. R. Hammond was awarded the premium, which, however, is merged in the commission for carrying out the scheme. Mr. Hammond's scheme is an alternating-current one, and includes the lighting of Queen street, Chapel-hill, and Church-street, but the license includes the whole of the borough, and will prevent private individuals setting up works in rivalry with the Corporation. A site in Fountain-street, directly opposite the Great Northern goods station, has been acquired by the Corporation for the erection of the generating station. From the central station high tension mains will be laid down Albion-street and Queen street, with transformer sub-stations at intervals. This work will be done by contract, tenders for which have yet to be received, and the work which is now being carried out is simply the laying of the pipes for the mains. The Electric Lighting Committee are endeavouring to arrange for some lighting to begin this winter by means of a temporary engine, but it will probably be next summer before the whole of the permanent works are completed.

Worcester.—In the agenda for the next meeting of the Town Council is the consideration of a long report referring to the disputes as to the electrically-driven pumps. Last spring Mr. W. P. Hughes resigned the chairmanship of the Water and Sewerage Committee "because he had lost confidence in the city engineer, owing to his reports as to the saving to be effected by the use of electricity for pumping at the waterworks not being borne out by the result of such use." The matter was referred to the Deputy Mayor (Hon. A. P. Allsopp) by the joint sub-committees of the Water and Sewerage and the Electricity Committees, who suggested the following points as those upon which information should be sought: (1) What was the city engineer's authority for the following advice given to the Council in his report of February 16 1894, "I have considered the matter very carefully, and although an estimate of this kind must necessarily be somewhat uncertain; I am of opinion that the proposed arrangement should at a moderate estimate yield a return of £600 a year for the outlay in the saving of fuel, while the expenditure would also result in the extension of the electric lighting main through a district likely to provide customers for the light." (2) Has such advice been justified by the result, to any and to what extent? (3) If not justified, then why not? Mr. Allsopp heard the city engineer, the electrical engineer, and other witnesses at an enquiry held on June 17, and at a meeting of the Joint Sub-Committees on July 8 submitted the following report, which was ordered to be printed: "In reference to the enquiry which was held by me, acting under the authority of your resolution of June 1, 1896, I beg leave to inform you that the city engineer, in advising the Council in his report of February 16, 1894, to adopt electricity for pumping at the waterworks, based his advice upon the result of calculations which, considering that they were confirmed by the consulting electrical engineer, constituted, in my opinion, ample authority for such advice being tendered to the Council. As regards the question whether this advice was justified, everything turns upon the interpetation to be placed upon this word Adopting a strictly literal interpretation, I have no doubt that the city engineer has shown that the reasons which induced him to give such advice to the Council were both adequate and sufficient. On the other hand, if a more popular interpretation be adopted, there is no doubt (and the city engineer himself admits it) that that portion of his advice which relates to the electric pumping has not been justified to any extent by the result. After a careful consideration of the facts which the enquiry brought out I am of opinion that the special circumstances at the electricity works and during the year 1895 are a sufficient reason why the original forecast of the city engineer has not been completely fulfilled. The extension of the electric lighting main has enabled the Corporation to obtain a small revenue from the supply of current for lighting purposes."

PROVISIONAL PATENTS, 1896.

AUGUST 24.

18669. **Improvements in means for suspending the electric conductors used in electric railways, tramways, and the like, known as the trolley wire.** Magnus Volk, 36, Eaton-place, Brighton.

Digitized by Google

18666. **Improvements in means for the construction of submerged or partially submerged permanent ways for cars driven by electricity, steam, or other motive power; also for steep grade permanent ways for cable cars and the like.** Benjamin William Clayton Botham, "Ravenswood," Stanford-avenue, Hassocks, Sussex.

18680. **Fixed-contact apparatus for use with railway electric brakes.** Hubert Georgin, 8, Rue des Princes, Brussels.

18704. **Improvements in connection with electric traction systems.** Herbert Allen and Oliver Peard, 55 Chancery-lane, London.

18711. **Appliance for preventing noise in wheel gearing of pumps, or any machine or machinery driven by electric or any other power.** William Wright, 8, Louvaine-road, New Wandsworth, London.

18730. **Improvements in or relating to alternate-current motors.** Valerè Alfred Fynn, 47, Lincoln's-inn-fields, London.

AUGUST 25.

18785. **Improvements in telephonic apparatus.** Carl Joseph Schwarze, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18786. **An improved system of control for electric motors.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Elmer Ambrose Sperry, United States.) (Complete specification.)

18830. **Automatic electrical indication of the names of stations in each separate compartment of trains in motion.** Frederic James Longton, Rosemont, Woolton Hill, Lancs.

AUGUST 26.

18839. **An electrical system of railroad and fog signalling. To be used in conjunction with the present system of railroad signalling.** Henry Gilhespie, "Rosebank," Station-road, Chingford, Essex. (Complete specification.)

18841. **The abolition of the commutator in continuous-current dynamos and motors.** Sidney Augustus Nash, 206, High-road, Kilburn, London.

18843. **Improvements in electrical switches.** Herbert Grace Richardson, 70, Deansgate, Manchester.

18867. **Improved electric trolley mast.** Ernest Kilburn Scott, The Elms, Bushbury-lane, Wolverhampton.

18878. **Improvements in gas-valves actuated by means of electrical energy.** The Midland Purchase Syndicate, Limited, and William Henry Gritton, and Walter Whitington, 55, Chancery-lane, London.

18889. **Improvements in electric light switches.** Andreas Peter Lundburg, 18, Regina-road, London.

18892. **Improvements relating to switch fuses or electric safety fuses.** Charles James Hall and Henry James Fuller, 433, Strand, London. (Complete specification.)

18907. **An electric coin-freed apparatus for dispensing liquid refreshments.** Harold Imray, 28, Southampton-buildings, Chancery-lane, London. (Octave Valdobra, Belgium.)

18908. **An improved writing desk or slab, more particularly applicable as an adjunct to telephone receivers.** Frederick Charles Lehfeldt and James Stevens, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

18912. **Improvements in or relating to telephone systems.** Moise Freudenberg, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, August 7, 1896, being date of application in France.)

18914. **An electrical means by which an hostile fleet or army may be rendered powerless.** Richard Joseph Crowley and William Olney Baker, 59, Chancery-lane, London.

AUGUST 27.

18951. **Improvements in electrical accumulators.** Alfred Conder and Edouard Paul Michelot, 8, Great Portland-square, London.

18968. **Improvements in current-actuated bell buoys.** Albert Louis Woodworth, 322, High Holborn, London. (Complete specification.)

18974. **A new or improved apparatus for electrically smelting metals, and for other like purposes.** John Laskey Dobell, 57, Chancery-lane, London.

18987. **Improvements in regulators for electric arc lamps.** William Robert Lake, 45, Southampton-buildings, Chancery-lane, London. (Agostino Ferrario, Italy.)

AUGUST 28.

19021. **A new or improved incandescent electric lamp.** Jean Renous and Boleslas Bronislawski, 64, Mark lane, London.

19045. **Manufacture of secondary galvanic elements.** Albrecht Heil, 28, Southampton-buildings, Chancery-lane, London.

AUGUST 29.

19114. **Improvements in automatic switch devices for electric currents.** James Thornhill Ashton, 111, Hatton-garden, London.

19148. **Improvements relating to electric current transformers.** William Robert Lake, 45, Southampton-buildings, Chancery-lane, London. (The Elektrizitats-Aktiengesellschaft vormals Schuckert und Co., Germany.)

SPECIFICATIONS PUBLISHED.

1895.

13957. **Trolley systems of electric propulsion and in apparatus therefor.** New.

14627. **Electric fire alarms.** Brown and Neilson.

15024 **Electrolytic production of amalgams and their utilisation.** Andreoli and Andreoli.

15895. **Electric contact making and breaking apparatus.** Quincey and Collins.

16521. **Overhead system of electric traction.** Bersey.

17063. **Electric smelting.** Willson (Date applied for under International Convention, February 20, 1895.)

18305. **Means of supporting and insulating electric conductors within culverts or like conduits.** Crompton.

18588. **Fusible cut-out or safety devices for electric conductors.** Partridge and Berry.

18935. **Apparatus employed in regulating electromotive force in alternating-current circuits for theatre lighting or other useful purposes.** Probert and Moy.

19353. **Electric gas lighting apparatus.** Jahnsson.

1896.

6480. **Rail bond for use on electric railways and for like purposes.** Turner.

12344. **Method of indicating at a telephone station whether the telephone lines are engaged or not.** Naglo.

13046 **Cleats for electric and other wires and the like.** Evans.

13264. **Regulating induction electric motors.** The British Thomson Houston Company, Limited. (Armstrong.)

13723 **Incandescence electric lamps.** Germer and Hüller.

14442 **Telegraphy** Essick.

15031. **Dynamo-electric machines and methods of compounding the same.** The British Thomson-Houston Company, Limited. (Steinmetz.)

NOTES.

Cable Extension.—The Dutch Government are proposing to lay a cable between Atjeh and Lombok, in the East Indies.

Obituary.—The death of Mr. R. W. Peregrine Birch, the civil engineer, is announced to have taken place at Foyers while he was on a visit to the works he was carrying out there for the British Aluminium Company.

Fatty Acids.—Mr. J. Hamonet has been studying the electrolysis of the mono-basic "fatty" acids, and from a communication to the Paris Académie des Sciences it appears that he finds that the results formulated by Kolbe are not always to be relied upon, and that non-saturated hydro-carbons may be produced instead of saturated ones. The matter has at present only a chemical interest.

Electro-Harmonic Society.—The concerts, which will be six in number, of the eleventh season of the Electro-Harmonic Society will be held on the last Fridays in September, October, November, January, February, and March. The committee, with a view to keep up the standard of musical excellence of these concerts, have decided to incur increased expenditure, but the members will be glad to know that their subscriptions will remain as before.

Prize Medals.—The programme of the prizes to be offered next year by the Société Industrielle of Mulhausen has been published in the *Revue de l'Electricité*. The society offers medals for the application of electricity to printing, for an installation of electric motors (this is confined to Alsace), for a motor capable of running at variable speeds, the extremes being in the ratio of 1 : 10 at least, for an improved method of attaching armature brushes, and, lastly, for papers on town and factory lighting.

Electric Fire Pumps.—Prof. Newcomb, in *Cassier's Magazine*, has a short article suggesting what he considers an ideal fire-extinction plant for mills. This consists of a pump, at a safe distance from the mill, capable of starting automatically and driven by a power independent of the mill, which in practice means driven electrically. A sprinkler system would be connected with a regulator, so that a fire would set to work some of the sprinklers under the influence of the heat, which would diminish the water pressure, this in turn acting on the regulator which starts the motor and the pump.

Motorcarts.—A gentleman who, though he signs himself "Rusticus," is obviously no countryman, or he would not talk about "Rosetti-land," has written to the *Daily News* to complain that a motorcart has gone down a lane. We have naturally no affection for the oil motorcart, but if no vehicle that could be heard or smelled—"Rusticus" talks about stench—were allowed in the country, agricultural operations would be restricted even in Arcadia. The manager of the Anglo-French Motorcar Company has been fined by the Epsom Bench for somewhat anticipating the coming into force of the Act.

Labour Troubles.—The threatened strike in the engineering and shipbuilding trade has fortunately been settled. The quarrel in the glass trade it appears is to be fought out, but this, compared with the other, is a very small affair. Lastly, the secretary of the Tailors' Improvement Association has appealed for help to a City company. The Master of the Merchant Taylors' Company replied that the powers of the company of forcible intervention in trade disputes "have not been exercised for many years." It may safely be said that few people know precisely what those powers are.

Another Submarine Boat.—According to the *Daily News*, a new submarine boat on Poukalov's system, whatever that may be, is approaching completion at Cronstadt, and will soon be put to its trials. The boat is to be driven by electricity, supplied by accumulators sufficient to last for a two hours' run, and is to have a speed of 10 knots an hour. Beyond the statement that the boat is adapted for travelling along the surface of the water and for submerging itself to a depth of not more than 7ft. by the aid of horizontal rudders, no further details are available.

London Telegrams.—It is well known that most of the telegrams sent from one part of Central London to another are not really telegraphed, but are blown or sucked through the pneumatic despatch tubes. The *St. James's Gazette* has suggested that this being so the Post Office should give up the farce of copying these messages off white paper on to pink as though they had been over the wires, and save time and labour and the opportunity of mistake by delivering them at once as they are written. The suggestion seems a sensible one, but that gives no guarantee that it will be speedily adopted. Something of the sort is, however, done in Paris.

Cost of German Education.—The British Consul-General at Frankfurt, in the course of a report, has referred to certain official information supplied to the Italian Government in regard to the cost of university study in Germany. From this it appears that at Berlin the cost of a civil engineer's course, including that of living, is estimated at 6,000 marks (say, £300) for four years. At other German universities the cost would be somewhat less, but the difference would not be very great, for the main item—the cost of living—is very much the same in all university towns. Foreign students often prefer the smaller universities, especially those in South Germany.

Physicians of the Future.—Last week's issue of the *Lancet* (September 5) is entirely devoted to the needs of these. It embodies the courses and calendars of the colleges and hospitals, with references to science colleges and other institutions as to which information may be of value to medical studends. It may be noticed that the name of Faraday House appears, but not the City and Guilds Institute. The position of the qualified English medical man who desires to practice abroad is also treated of, and this article is interesting, as showing the different spirit in which the subject is dealt with in different countries, whether with a view to the protection of the public or of the local medical profession. Germany, as usual in scientific matters, sets a good example. There, apparently, you may do as you like about having a German doctor or one of your own nationality, only the latter must not stick any letters after his name which would make people think he had a German qualification. That is rigidly suppressed, and with reason. Austria, on the other hand, requires a 10 years' residence and naturalisation, and France does not make things too easy. In general the Colonies are contented with a registration fee.

Submarine Boats.—The *Bulletin* of the French Society of Civil Engineers contains Mr. G. L. Pesce's paper on submarine navigation. Mr. Pesce goes to the form of deep-sea fishes to obtain the proper shape for a submarine boat, and in his history of the subject starts from the time of Demetrius Poliorcetes. We may, however, begin by skipping 21 centuries, more or less, and start fair with the year 1796. It appears that since that date about 60 designs for submarine vessels have been brought out, and most of them have got as far as actual construction, so that on an average the submarine boat is invented twice

Digitized by Google

in every three years. It is needless to say that since the discovery of the storage battery electricity is usually chosen as the motive power. Mr. Pesce does not claim to have given a complete list, and the boats are practically in all cases designed as instruments of warfare. Nevertheless, the author concludes his paper with the remark that he has a profound conviction that the question of submarine navigation will in the very near future be settled from a commercial rather than a warlike point of view, to the great profit of civilisation and universal peace. How the latter is to be promoted by fighting under water instead of on the surface is not altogether clear.

Cost of Arc Lighting.—A preliminary report of the National Electric Light Association on arc lighting statistics, embracing about 400 cities and towns of the United States, having a population of 5,000 or more, has been issued, and is summarised in the *Electrical World*. The report gives for each town the number of arcs, candle-power of each, price per night, and the time of burning. There appears to be a wide variation in the cost of street lighting, one municipal plant reporting a cost of 36dol. per year for 1,200-c.p. lamps burning seven hours per night "under a moonlight schedule," while the price paid in one of the largest cities is 182·50dol. per year for the same candle-power arcs burning all night. The report shows that the rates in four municipalities are above 180dol. per annum, while in one municipality above 170dol., in five above 160dol., in six above 150dol., in nine above 140dol., in 10 above 130dol., in 31 above 120dol., in 28 above 110dol., in 58 above 100dol., in 73 above 90dol., in 61 above 80dol., in 64 above 70dol., in 34 above 60dol., in 14 above 50dol., and in nine above 40dol. Of the 33 municipal plants mentioned, 10 failed to report, and of the remaining 23 which reported, the cost for nine ranges from 50dol. for 1,500-c.p. arcs to 96dol. for 2,000-c.p. arcs, burning all night, and for the remaining 14 from 36dol. for 1,200-c.p. arcs to 70dol. for 2,000-c.p. arcs burning on a moonlight schedule.

Cornell University. — We have received from Ithaca, New York, the programme of the instruction in physics at Cornell University. The experimental and laboratory work seems very full. Beginning with elementary mechanics and electrostatics, the student in the first year gets as far as batteries. The second year is devoted to continuous currents and the third to alternating currents and photometry. There appears, however, to be no reference to polyphase-current work. Work in applied electricity is carried on in a building arranged for the purpose. On the lower floor is the dynamo laboratory of the department, a room 35ft. by 100ft. It contains two main lines of shafting, extending the entire length of the room and each driven by an electric motor of 50 h.p. More than 40 dynamos and motors of various types and sizes are in constant use for experimental purposes, and there are available also large batteries of accumulator cells (about 150 cells). Alternating currents of various potentials are obtained, by means of specially constructed transformers, directly from the lines of the public supply company. The upper floor of this building contains laboratories for electric light photometry and for various studies in electro-technics. In the post-graduate courses ample provision is made for the teaching of the higher mathematics, including some of the modern methods, which are still, as it were, admitted under protest and only to advanced students on this side of the water.

Electrolysis in Sugar-Making.—Among the matters dealt with at the Paris International Congress of Applied Chemistry was the application of electrolytic methods to the purification of sugar solutions in the course of manufacture. According to the *Journal des Fabricants de Sucre*, Mr. L. Battut, of the Arleux Works, started the discussion with a *résumé* of the various methods adopted. His conclusion was that for purification work electrolysis was a feeble method to depend upon, and was practically useless, except for decoloration. In conjunction, however, with dialysis it might be useful. His experience was principally derived from laboratory work. On the other hand, Mr. Baudry said that in actual practical work in the production of beet sugars in Russia, simple electrolytic processes had proved most valuable. The current was applied after the addition of lime in the usual way and defecation. Messrs. Aulard and Battut objected to Mr. Baudry's theory of the process, which was that the current broke up the non-saccharine constituents of the solution. Prof. E. Peyrusson, of Limoges, raised what seems a reasonable protest against the use of lead anodes. (Lead would be a most convenient metal to use in sugar manufacture in another way if it were not for the danger of lead-poisoning from traces remaining unremoved in the finished product.) Mr. F. Dupont (the secretary of the congress), however, did not join in this fear. If the purification process was not pushed too far, there would be no danger of the lead going into solution. He was not, however, prepared to say that the electrolytic process was as yet a practical one, but he did not despair of it becoming so.

Gas and Electricity.—Mr. D. M. Dunning has an article in the *Engineering Magazine* on the subject of "Gas *v.* Electricity direct from Coal." The latter part of the title refers to the Jacques cell, in which he sees no cause for fear on the part of the gas interest. In this we quite agree with him, though not for the same reasons. Mr. Dunning's general conclusions on the position of the gas industry in America in the face of electrical competition are more interesting. He admits at once "that the day has certainly gone by when the gas manager can sit quietly around and allow his works and business to run him. He must now reverse things—run the works and push the business; and so thoroughly has this become recognised that the industry, where properly managed, has already become one of the most prosperous in the land. It has held its own through the shrinkage of values and financial reverses of the past few years better than almost any other, and, where it has kept clear from electrical entanglements, has paid its dividends with surprising regularity. In the way of the utilisation of residuals and illumination through incandescent lamps, it has, through the aid of science, made most rapid advances, and still presents, in these and other lines, the broadest fields for scientific research and investigation. At various times it has, in the minds of many, been threatened with serious, if not fatal, competition from electricity; yet the gas industry is probably to-day in a healthier and more prosperous condition than it would have been if electricity had never been a competitor, because the electric light has created a demand for more light and a stronger light, which, together with its competition, has stimulated the gas industry to improvement, and to advance and extend its business; and on these lines, and with the aid of lower prices, the future manager seems to have an almost unlimited field."

British Association (General).—The secret of the president's address is well kept, but more "forecasts" have been published as to what is to take place in the sections. Biology in general we pass by, but in the Zoological Section we are to have the age of the earth again. For many years there has been a standing quarrel between the physicists and the geologists on this subject. The former have a strong case, but have on the whole

Digitized by Google

been unlucky. Very early in the dispute Lord Kelvin made a curious misinterpretation of the meaning of one of his mathematical results, and when Mr. George Darwin tried to arbitrate the question in favour of the heat-people with the help of the moon his work was popularised in such a manner that the average geologist might easily believe it to be as incapable of supplying an accurate time gauge as his own inexact science. The result of it all is that, instead of the modest 200 millions of years—that is all that physical investigation seems to allow him—he has gone on asking for millions of millions of years, and now we have Prof. Poulton asking on behalf of the zoologists for a still further extension, in order to account for what must have occurred previous to the history which we find in the fossiliferous strata. But things might have gone a bit quicker in those days. At the meeting of the Douglas Town Council the Mayor (Major Stephens) said that he had consulted Dr. Gill and others representing the Antiquarian Society as to giving a conversazione on the occasion of the visit of the members of the British Association to the Isle of Man on the 26th inst. The Mayor undertook, with the consent of the Council, to defray the expenses of the conversazione, which he proposed to hold in the School of Art. He said about 200 members were expected from Liverpool. Lord Henniker (the governor of the island) had promised to attend, and probably the Earl of Derby would be present. The Council unanimously passed a resolution endorsing the Mayor's action, and promising their support.

A Suffolk Suggestion.—Bury St. Edmunds is not in all respects like other towns of the same size in the way things are done there, and the existing distinction is apparently to be preserved in the matter of electric lighting. Not content with having a scheme that reverses the ordinary proportion of the areas of private and public incandescent lighting, the Town Council have elaborated a proposal in connection with the financial portion of the work that is so entirely novel that it appears to have been entirely misunderstood by everyone outside the borough. Certain ratepayers threatened to oppose the scheme for fear it might increase the rates, whereupon the members of the Electric Lighting Committee proposed to form a private company—not to do the electric lighting, but to indemnify the borough if the enterprise proved financially a failure, and to take all the profit if it proved a success. The town was to find the money, do the work, and apparently manage the business, but the gain or loss was to go to the company. The town clerk, on being appealed to for his opinion on this way of doing things, declined to give one without consideration. As he had had his advice on a much simpler matter overruled, we think he was wise. But he referred the matter to his parliamentary agent, Mr. E. E. Baker. That gentleman "had never heard of such a proposal," and thought "the scheme would be quite unworkable unless the Corporation had an absolutely free hand as to the price to be charged for lighting." Obviously, if the Council fixed the price low enough, there would be no profit, and a loss would not matter, since the company would have to indemnify it. Mr. Baker's advice on the subject substantially amounted to telling the Town Council, if they determined to persist with their proposal, to "try it on" first with the Board of Trade by inserting special clauses in their electric lighting order. Having got the consent of the Board of Trade, the Local Government Board might possibly be induced to pass the necessary loan. We should be inclined to doubt it, although the gain is all on the side of the Corporation. Municipal and Government guarantees are common enough abroad, and we have got as far as admitting the principle here in connection with light railways, but a private company guaranteeing a municipality is somewhat of a reversal of the usual order of things.

An American on Labour. — Under the title of "Modern Machine Shop Economics," Mr. H. L. Arnold, who once was a journeyman machinist, contributes an article to the *Engineering Magazine* on the subject of first principles in the management of men. It is practically a plea for piecework, with, as we understand it, an additional premium on the number of pieces turned out. It is not very clear how the workman is made to understand that what he fears will not come about—namely, that when a piece price has produced a greater output and earning, it may be cut down—but this is implied somehow or other. Mr. Arnold, however, treats trade union and class feeling generally in a way to make a labour leader's hair stand on end. For instance, he says: "The typical wage-earner is, first of all, incapable of managing any business, even his own, much more that of an assemblage of his fellows. Many large employers have, indeed, come out of the workshop, but they came out early in life; they never were union or trade society men." This, however, is not confined to "working men," but is an all-round business. Mr. Arnold, for instance, says, "Work for wages merely is vile, and vilely degrades the worker." As wages here must obviously include salaries, stipends, "retainers," or what not—in fact, any remuneration fixed in amount and paid every week, month, quarter, or year—it would seem that there must necessarily be a great deal of vileness and degradation in many branches of the commercial and professional world, while the prospects of the gentlemanly "services" are perfectly hopeless. Unfortunately for the adoption of Mr. Arnold's plan, all masters are not, any more than all workmen, either angels or philosophers, and competition tends to level the best down to the standard of the worst, or, at any rate, is believed to do so, which in practice comes to the same thing. The article, however, if it somewhat ignores the other side of the question, is not without a basis of sound sense, and whether the views expressed were right or wrong, it would all the same be worth notice from the vigorous way in which they are enunciated. Moreover, Mr. Arnold does not, like many people, draw arbitrary lines as to how far his principles should be carried out. Though he obviously hates the idea, he is, for instance, quite prepared to see women at work in the machine shops.

High-Frequency Currents.—The following is from an article by Mr. J. Tuma, in *Beiblätter*, on the subject of measurements with alternating currents of high frequency, which has been published as an abstract in the *Journal* of the Institution of Electrical Engineers: "The author gives a method whereby measurements of resistance can be made with oscillating currents. When a rapidly alternating current flows through a conductor of very small cross-section, it may be assumed that the current-density is uniform over the whole cross-section. If the heat generated—which in this case is due to the oscillating current—be measured, and also that generated by the passage of a continuous current through the same conductor, the amount of heat generated in each case, in equal times, will be in the proportion of the mean squares of the current-strengths. A conductor of very small cross-section can also be used for the measurement of the intensity of oscillatory discharges. If a thick wire, B, be put in series with the wire, A, of small cross-section, the relation between the amounts of heat generated in the two wires when continuous currents of different strengths are passed through them, remains constant; this, however, will, generally speaking, not be the case when oscillating currents are passed through the

Digitized by Google

wires. If W be the heat generated in the wire B, and W_1 that generated in the wire A when the wires are in series with one another, and a continuous current of intensity J is flowing through them for a time *t*, and W' and W_1' the corresponding quantities of heat generated by the application of an alternating current of intensity J' during a time *t'*; moreover, let w_1 be the resistance of the wire A_1, *w* the resistance of the wire B for the continuous current, and *w'* that for alternate currents: then we have

$$\frac{w'}{w} = \frac{W'}{W_1'} \cdot \frac{W_1}{W}, \text{ and } J' = J\sqrt{\frac{W_1' t}{W_1 t'}}.$$

If a Bunsen ice calorimeter be used, and l, l_1, l', and l_1' be the corresponding distances through which the meniscus in the capillary tube of the calorimeter is moved, then

$$\frac{w'}{w} = \frac{l'}{l_1'} \cdot \frac{l_1}{l}, \text{ and } J' = J\sqrt{\frac{l_1' t}{l_1 t'}}.$$

From the combined results it is deduced that the ratio $\frac{w'}{w}$ increases with increased thickness of the conductor, and with the frequency of the current. From measurements on German-silver wires it was found that the ratio $\frac{w'}{w}$ approached nearer to unity as the specific resistance increased. That the resistance was dependent on the current strength was very noticeable, especially in a 2mm. and a 3·1mm. thick iron wire."

Local Government Board Enquiries.—The *East Anglian Daily Times* apparently objects to too much evidence being taken at a Local Government Board enquiry. Referring to the application of the Colchester Town Council for leave to borrow money for electric lighting, it is remarked that "there seems nothing to prevent the opponents of a particular scheme from arguing against it a second time when the inspector holds an enquiry, as if the town were governed, not by the Corporation, but by the Local Government Board." This, it is contended, ought not be possible. But the object of the enquiry is surely to prevent future ratepayers, who are as yet not in existence and cannot be heard, being burdened with an expenditure which they would never have consented to. Obviously that is a task which can only be performed approximately, and it does not appear how it could be performed at all unless the Board was willing to take all the evidence it can get as to whether the scheme is a good or a bad one. The case of one of the opponents, a farmer, deserves more sympathy than is usually accorded it. The nominal boundaries of some East Anglian boroughs stretch out far into the country, and include villages which derive no benefit from the town improvements they have to pay for. It is no doubt small comfort to Mr. Blyth to know that because Colchester was reckoned a half-hundred in the days of Athelstan, and that in those days it was worth paying to the borough scat to get the protection of the old Roman walls when the Wikings were abroad, his land must now take its share of the cost of municipal improvements, including electric lighting. He will be better pleased to learn that the Colchester scheme looks about as moderate and reasonable a one as could well be, and so far as is possible to judge in those matters is not likely to increase his rates, and may possibly diminish them. At Mitchelstown, in Ireland, the case of Mrs. Ellen Coghlan's cows, which "do not require the electric light to graze by," can be met by varying the area of taxation, but this does not appear to be possible in England. The Colchester enquiry also produced a gentleman who had "seen electric lighting worked successfully in the centre of Africa," and whose idea of success seems to be 2½d. per unit. This must be looked to. Up to the present the only information we have been able to obtain as to electric installations in the centre of Africa has been derived from the *Bier Zeitung*, published under the auspices of the Verband Deutscher Elektrotechniker.

Village Lighting.—The difficulties of a very small gasworks are not inconsiderable—that is to say, if a good quality of gas is to be supplied at a reasonable rate. On the other hand, though it has been contended that a small electric light installation need not in the nature of things be worked only at excessive cost, very little has been done practically in the way of supplying the needs of the large villages and small growing towns that have not already been taken up by the gas companies. In spite of the obvious advantage of having a free field, instead of endeavouring to turn out a company already installed in the streets and houses, and in possession of the sympathies of the local shareholders, it has apparently been thought that in the large village the game is not worth the incandescent lamp, and such places have in general been left to make their choice between the in every way troublesome and unsatisfactory petroleum lamp and unrelieved darkness. There are, of course, exceptions. For instance, some time ago we noted in this journal the introduction of the electric light into Mevagissey, where the population of the whole parish only a little exceeds 2,000. The progress of the company founded by Messrs. Veale, of St. Austell, to try how electric lighting will answer the needs of a fishing village on the South Cornwall coast will therefore be watched with interest. The place had been without public lighting of any kind. The generating station consists of a shed, containing a Paxman semi-portable engine, a Crompton dynamo, and a set of accumulators, while a few 16-candle incandescent lamps on wall brackets constitute the public lighting. Sufficient private business has already been secured to give full employment to the present engine power during the winter. The supply is by meter, at 6d. per unit, so that the village enjoys a cheaper service than the City of London. Whether or not the undertaking will pay dividends, of course, is yet to be seen, but the whole affair is an example of strictly economical electrical engineering, and the working appears to have given satisfaction. All the proposals made—and there have been more than one—for setting up a gas undertaking in Mevagissey have come to nothing; so that the little electric light company has undertaken a work which, as the *Journal of Gas Lighting* confesses, the most venturesome of contracting gas engineers have either overlooked or shrunk from.

British Association (Section A).—At the British Association it is the proceedings of Section A that primarily concern our readers. The following gives practically a programme of what is to be done in that section, though of course there will be some additional papers besides these enumerated. The section will meet daily at ten o'clock, and the committee meetings are at two. The reports of committees are nine in number, and deal with: (1) Electrical Standards (special report on a thermal unit); (2) Magnetic Standards; (3) Comparison and Reduction of Magnetic Observations; (4) the Establishment of a National Physical Laboratory; (5) Meteorological Observations on Ben Nevis; (6) Seismological Observations; (7) Calculation of the $G_{(r,\,\nu)}$ Integrals; (8) Mathematical Tables; (9) Solar Radiation. Among the papers we have first a group dealing with the kinetic theory of gases, on which there has been some very considerable criticism recently on the Continent. The first of these is by Lord Kelvin on "The Molecular Dynamics of Hydrogen Gas, Oxygen Gas, Vapour of Water, Water and Ice." Mr. G. H. Bryan entitles his paper "Some Difficulties Connected

Digitized by Google

with the Kinetic Theory of Gases"; and Mr. S. H. Barbary's is "Stationary Motion of a System of Equal Elastic Spheres." The purely electrical papers include one on "The Division of an Alternating Current in Parallel Circuits with Mutual Induction," by Mr. F. Bedell, and others will be read by Mr. W. M. Mordey "On an Instrument for Measuring Magnetic Permeability"; by Mr. E. H. Griffiths on "The Measurement of Electrical Resistance"; and by Mr. W. H. Preece "On Disturbances in Submarine Cables." There will be also two others, of which the joint authors are Lord Kelvin and Mr. Magnus Maclean, which will deal with "The Communication of Electricity from Electrified Steam to Air," and "The Measurements of Electric Currents through Air at different Densities, down to the five-millionth of the Density of Ordinary Air." There is also a paper on "A Complete Apparatus for the Study of the Properties of Electric Waves," by Mr. J. Chunder Bose. It can hardly therefore be said that electricity does not have its fair share in the work of the section. The other papers are by Mr. S. A. Sworn, on "Researches in Absolute Mercurial Thermometry"; by Mr. W. E. Plummer, on a "Comparison of the Results obtained from the Records of Certain Anemometers"; by Mr. G. H. Bryan on the "Sailing Flight of Birds"; and pure mathematics is represented by a paper by Lieutenant-Colonel Cunningham, R.E., on "Connection of Quadratic Forms." There will be various papers on the Röntgen radiations, as to which particulars are not at present obtainable, and the whole of Friday is to be given to this subject. It is to be hoped, therefore, that the proper theory will be finally settled, though, of course, there should not now be very much doubt on the matter. These are the only papers on light, and it appears as though there would be none at all on acoustics. Perhaps that subject is considered to be exhausted for the present.

Scientific Education.—During the last week quite a quantity of important people have had something to say in the columns of the *Times* on the subject of scientific education in general and the production of competent chemists in particular. Sir Philip Magnus would spare the secondary technical schools. His remedy is to reorganise the London University. The primary need in organisation is the concentration of the teaching power of any one faculty in one institution. "Such organisation of the higher teaching, in the chemical faculty especially, is indispensable if English manufacturers are to be supplied with competent English chemists." Mr. R. J. Friswell says the average pay of the chemists in the great German aniline colour factories largely exceeds anything of the kind paid in England. "The German willingly pays and waits for results, often for years. The Englishman expects immediate results or the departure of the unfortunate chemist. But the great point is that, as Carnot organised victory, so the Germans have organised industrial research. With armies of chemists ranging from 100 downwards, they are able to place a force of thoroughly equipped men in properly furnished laboratories to follow up any line of research likely to yield results." The next voice comes from Oxford, of all places in the world. It is that of Mr. J. E. Marsh, who says scientific education in this country is in a bad state, not so much that it is inferior in method, but rather because it is considered inferior to classical and mathematical education. "Until our public schools and colleges recognise that science is to take its place in their curriculum on an equal footing with other subjects we cannot expect our manufacturers, saturated at school with Greek and Latin, to recognise the value of scientific research." This is a true witness. A controversy of this character would not be complete without Prof. Silvanus Thompson. On the subject of the frittering away of funds upon a host of inferior schools, Prof. Thompson says: "It is ridiculous to suppose that a smattering of chemistry given to 10,000 boys in 500 different centres can have any appreciable effect in the chemical industries as compared with that which might be effected by spending the same money on thoroughly training 100 young men in five highly-equipped modern laboratories. The absorption by Germany of our chemical industries is being effected, not by giving evening instruction to boys, not by science-teaching in courses lasting two years, but by giving men a first-rate laboratory education, lasting four, five, six, or even seven years, under the most eminent chemists of the day. These are the skilled tools whom the German manufacturer finds ready to hand and employs to develop his processes of manufacture." Of Prof. Thompson's 100 young men, perhaps 80 would make no valuable discoveries. The only way to find your true researcher is to set him researching. It is essentially an article not producible by education alone. The conclusion of Prof. Thompson's letter is important. The best teaching will not save our trade if it comes too late. "There is no question that in the future electricity will enter largely into the chemical manufactures. Already the electric refining of copper has practically superseded the older metallurgical processes, and for the manufacture of bleaching liquid, of chlorate of potash, of aluminium, of caustic soda, the use of electricity is extending every day. Under these circumstances one would have supposed that every first-rate technical college would have anticipated the coming time by establishing special electro-chemical laboratories and by appointing a special instructor in electro-chemistry. What are the facts? In Germany three at least of the universities have already created professorships of electro-chemistry, and large electro-chemical laboratories have been erected at three of the universities besides that previously existing at Frankfurt. In England, so far as I am aware, there exist only two small electro-chemical laboratories—one at the Technical College, Finsbury, one at the Municipal Technical School at Birmingham—and both of these are devoted to instruction in electroplating and typing rather than to research in electro-chemistry. As for the rest of the science colleges in England, they are too busy with preparing pupils to pass examinations or are too poor to be able to undertake any such new departure." The last lines go to the root of the matter. The original "Chemical Manufacturer" has another letter. We learn from it that he comes from Manchester, and employs "several research chemists." His anonymity is therefore getting much thinner. Lastly, Prof. Tilden has something to say, but as he takes a column and a half of the *Times* to do it, we regret that we cannot get it all into this note. Briefly, he agrees with Mr. Marsh. If the nation chooses to endow, and honour and admire "the elegant imbecility of classical learning" in comparison with science, science will naturally suffer. "In Germany the university professor is a great man, well paid, received at Court, and honoured by all classes of the community, and this because he is an eminent man of science. In England a few chairs are pretty well paid, the majority very badly, and the public regard professors generally as unpractical dealers in useless wares." The general ignorance of our manufacturers is astonishing, and the current remedy of "technical instruction administered in moderate doses to the workpeople," and certain speeches at the London County Council, are beyond his patience—as well they may be. That is all for the present. What more the fates have in store for us next week time will show.

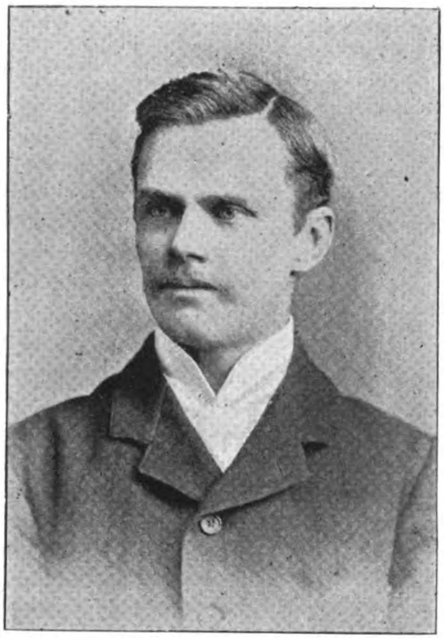
SOUTH SHIELDS ELECTRICITY WORKS.

(Continued from page 263.)

We are able, through the courtesy of the borough engineer, to give the accompanying view of the engine-room (Fig. 7). The day-load engine, with the alternator at one end and the spare exciter at the other, is shown in the foreground, while the large units are at the back. From



MR. JOSEPH A. JECKELL, A.I E E., BOROUGH ELECTRICAL ENGINEER.

this a good idea of the details of the engines can be obtained. It will be noticed that the engine-room staff have a high opinion of their personal beauty, and prefer front seats when photographs are being taken.

DISTRIBUTING SYSTEM.

As mentioned in our last issue, the distribution is carried out on the high-tension system, with transformer substations. The whole of the cables were supplied and laid by the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, of Silvertown. The high-tension main (see Fig. 1) is designed as a ring, which can be divided at five points. These points are in the transformer boxes. The cable used is $^{19}/_{16}$ concentric, with rubber insulation, except in the case of Ocean-road, where $^{19}/_{18}$ cable is used. The cables are drawn into 3in. cast-iron pipes.

The low-tension mains are single-rubber mains of ·1 square inch and ·15 square inch sectional area. These are laid in 2½in. cast-iron pipes. When it is desired to connect house services, the cast-iron pipe is cut and a joint-box (Fig. 8) bolted on to the pipes, in which a mechanical joint is made. The joint-box is then run up solid with compound. This system is a patent of Mr. Jeckell's, and it is claimed that it combines all the advantages of laying cables in cast-iron pipes and armoured cables in the ground.

In case the cable fails and has to be taken up, it can be withdrawn between two house services without disturbing the street. Again, the joint can be as easily made in this system as in the case of the armoured cable laid direct in the ground, as it takes no longer to cut the cast-iron pipe and bolt the joint-box on than it does to cut armour off the armoured cable. Any kind of cable can be used with this box, either concentric or single. Samples of these joints have been submitted to a pressure of 2,500 volts, so that there is no fear of a joint failing at the low-tension pressure of 110 volts. The cables which supply the current to the arc lamps are single rubber-covered cables, $^{7}/_{14}$, and are drawn into the same pipes as contain the high-tension concentric cable. Fig. 9 shows the drawing-in box on the high-tension side. The cables are in all cases insulated with pure and vulcanised indiarubber, and the high-tension cables, in addition to the ordinary conductivity and insulation tests, had to be subjected to a high-pressure test at 5,000 volts both before leaving the works and after they were laid and connected up. The tightness of the system of pipes was tested by an air pressure of about 10lb.

The ring main will in general practice be divided with one and supplied from the two feeder panels of the switchboard. We are rather surprised to see that Mr. Jeckell has used two single cables in iron pipes for the low-tension side, where an induction drop is most to be feared.

TRANSFORMERS.

The transformers were supplied by Messrs. Ferranti and Co., and are of the automatic type. They are placed in boxes sunk in the street, and these boxes are in every case sufficiently large to hold a 30-kilowatt transformer

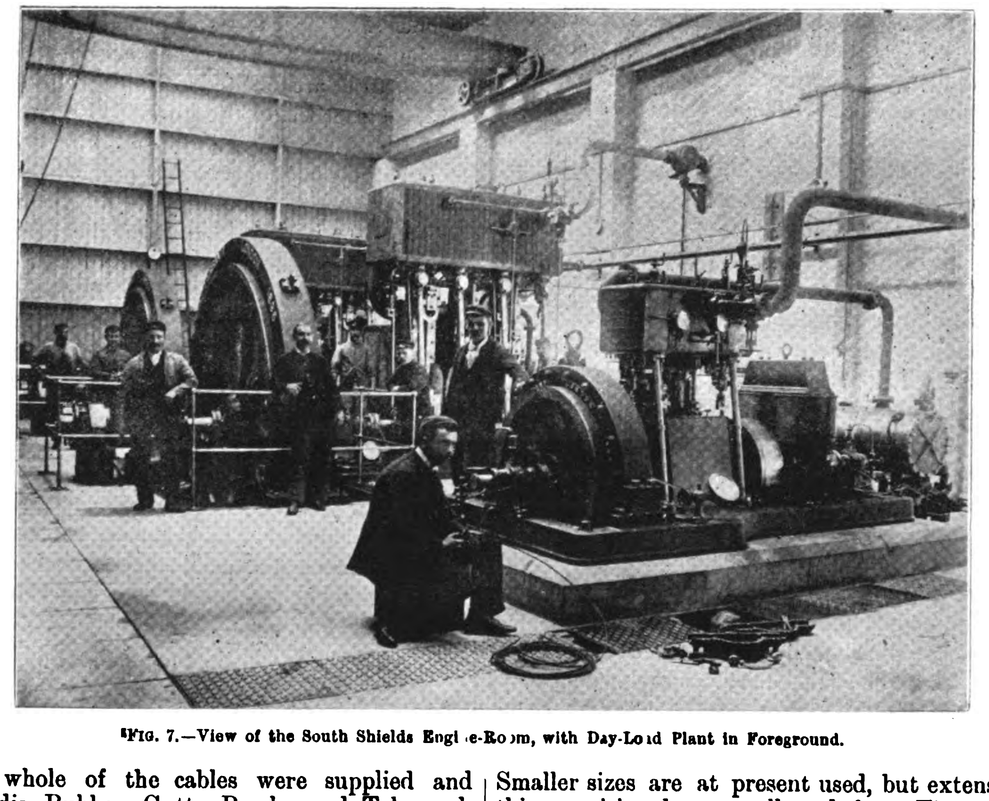


FIG. 7.—View of the South Shields Engine-Room, with Day-Load Plant in Foreground.

Smaller sizes are at present used, but extension can with this provision be easy allowed for. The system of automatic transformers is based on the patent issued some years ago to Mr. Ferranti. The primary and secondary winding are both subdivided, so that the sections normally in parallel can be put in series at times of light load. In

Digitized by Google

this way the iron loss is reduced very considerably, and the lightly loaded periods of the day are not so expensive in coal consumption. The transforming ratio of these transformers is 2,000 volts to 100.

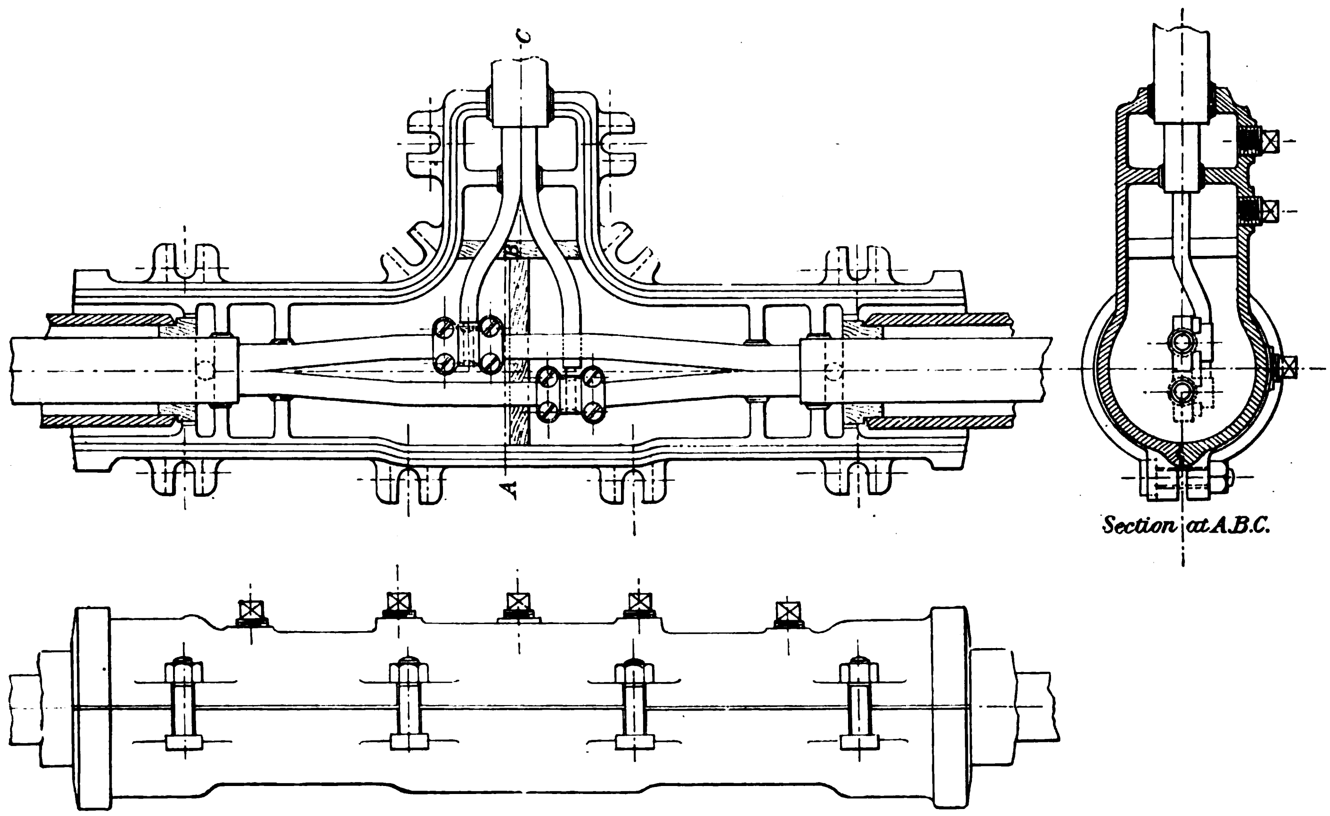

FIG. 8.—Low-Tension House Connection Box.

As mentioned in our last issue, the borrowing powers authorised at South Shields extend to a sum of £28,000, and up to the present only some £20,000 have been spent. Thus the committee have a good sum in hand for extensions, and will be able to foster the demand in likely districts by facilities for connections beyond the present network.

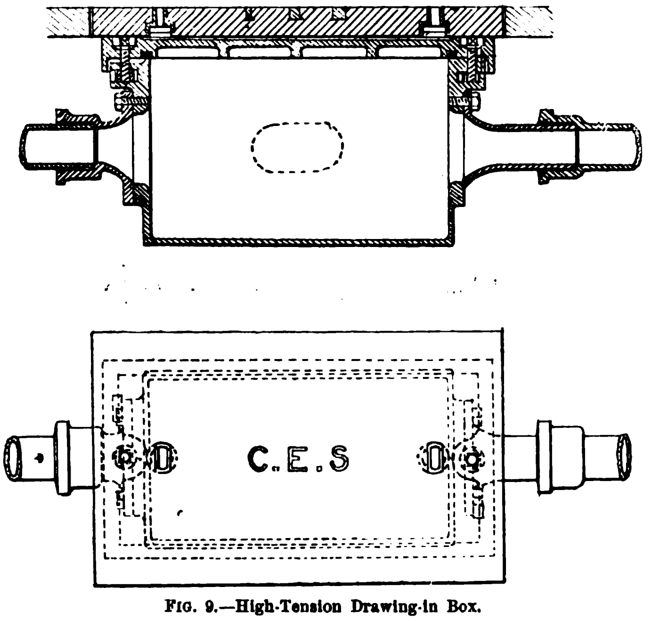

FIG. 9.—High-Tension Drawing-in Box.

The following list of contract sums shows approximately how the money has been spent:

Black, Hawthorn, and Co., boilers and pipes	£1,809 0 0
H. Watson and Sons, feed and condensing pumps ...	905 14 3
S. Z. de Ferranti and Co., engines, alternators, and switchboards	3,003 0 0
India Rubber, Gutta Percha, and Telegraph Works Company, cables and street work	4,846 0 0
S. Z. de Ferranti and Co., arc lighting plant	793 11 0
W. H. Brown, building	3,124 15 0

SCALE OF CHARGES.

The committee at South Shields have decided, under advice from their engineer, to fix the price per unit at 6d. for lighting purposes. A rebate will, however, be given to regular consumers. We gather from the interesting pamphlet that Mr. Jeckell has issued that maximum demand indicators will be used. After a consumer has burnt his maximum demand on an average for two hours per day, he will obtain all the rest of the electricity he requires at half-price—*i.e.*, at 3d. per unit. In order to give every facility to consumers desirous of using motors, the Corporation have also decided to charge the very low price of 2d. per unit for current supplied to motors.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 270.)

56. In the preceding articles, we have made no special assumption regarding the shape of the E.M.F. or current wave when discussing the measurement of these quantities. We shall now investigate some special relations which hold for simple sine waves.

We shall in the first place consider the *mean* value of a simple sine function. Since every sine function is capable of being exhibited as the product of a certain constant quantity (the *amplitude* of the sine function, Art. 14) into the sine of an angle which varies at a constant rate with the time, it will be sufficient to determine the mean value of the sine. From this the mean value of the function may be obtained by multiplying by the amplitude (which is the *maximum* value of the function).

Let, in Fig. 47, O P be a line of constant length which, starting from the initial position O A, revolves round O with constant angular velocity. The mean value of the sine of the variable angle A O P over a half-period is obviously the same as its mean value over a quarter-period. Taking, then, the arc A B, which corresponds to a quarter-period, we divide it into a large number n of very small equal parts. If O P $= r$, then the length of the arc A B is $\frac{1}{2}\pi r$, and the length of each division is $\frac{1}{2n}\pi r$. In order to obtain the *mean* value of the sine, we determine its value at the

* Based on a series of evening lectures delivered at the University College, Liverpool.

Digitized by Google

middle point of each division, add the values so obtained, and divide the sum by the number of divisions.

Let C D be one of the divisions, P its middle point. Then $CD = \frac{\pi r}{2n}$. Also, since C D is very small (although in the diagram, for the sake of clearness, it is shown fairly large), we may suppose that it is a short straight line. From C, P, and D respectively draw three straight lines at right angles to O A, and from C draw C E parallel to O A. Then, on account of the similarity of the triangles P_1OP, and E D C, we have

$$\sin P_1OP = \frac{PP_1}{PO} = \frac{CE}{CD} = \frac{C_1D_1}{CD}.$$

The same relation will hold for any other division. If we now take the sum of all the sines so obtained, it is evident that, on account of the length C D being the same for each division, this length will be a common denominator for all the fractions representing the sines. The sum of these fractions will therefore be simply the sum of their numerators, divided by C D. But the sum of the numerators gives us simply $AO = r$, so that the sum of the sines is

$$\frac{r}{CD} = \frac{r \times 2n}{\pi r} = \frac{2n}{\pi}.$$

Dividing this sum by the number of divisions, n, we find for the mean value of the sine $\frac{2}{\pi}$. Hence

The mean value of a simple sine function is equal to its maximum value, multiplied by $\frac{2}{\pi}$.

Since $\pi = 3{\cdot}1416$, we thus see that the mean value of a sine function is about ·637 of its maximum value.

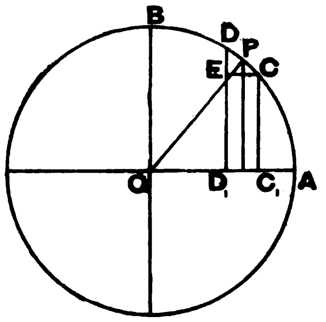

FIG. 47.

57. We have next to consider the R.M.S. value of a sine function. As before, this may be obtained from the *maximum* value by multiplying by the R.M.S. value of the sine. In order to determine the latter, we notice that the relation

$$\sin^2\theta + \cos^2\theta = 1$$

holds for all possible values of the angle θ (Art. 8.). From this it at once follows that

$$\text{mean value of } (\sin^2\theta + \cos^2\theta) = 1,$$

or, $\qquad$ mean value of $\sin^2\theta$ + mean value of $\cos^2\theta = 1$.

Now, since the cycle of changes through which the cosine of an angle passes is precisely the same as the cycle through which the sine passes, it follows that the mean value of $\cos^2\theta$ is the same as that of $\sin^2\theta$. We therefore have

$$\text{mean value of } \sin^2\theta = \text{mean value of } \cos^2\theta = \tfrac{1}{2},$$

and the R.M.S. value of the sine or cosine is thus seen to be $\frac{1}{\sqrt{2}}$. Hence

The R.M.S. value of a sine function is equal to its maximum value divided by $\sqrt{2}$.

Since $\sqrt{2} = 1{\cdot}414$, $\frac{1}{\sqrt{2}} = {\cdot}707$, and we see that the R.M.S. value of a sine function is ·707 of its maximum value. Comparing this with the result obtained for the mean value (Art. 56), we see that the R.M.S. value of a sine function exceeds its mean value by an amount which is about 10 per cent. of the former. The *form factor* (Art. 53) for a sine function is $\frac{{\cdot}707}{{\cdot}637} = 1{\cdot}11$.

58. We now pass on to the consideration of the *power* in an alternating-current circuit. At any instant the power is given by the product of the impressed E.M.F. into the current. Our object is to determine the *mean* power over a period. We shall, in the first place, consider the mean value of the power in a circuit whose inductance is negligible. In such a circuit we have at any instant

$$\text{current} = \frac{\text{E.M.F.}}{\text{resistance}},$$

$$\text{so that R.M.S value of current} = \frac{\text{R.M.S. value of E.M.F}}{\text{resistance}}.$$

Again, we have at every instant

$$\text{power} = \text{E.M.F.} \times \text{current} = \frac{(\text{E.M.F.})^2}{\text{resistance}}.$$

$$\text{Hence, mean power} = \frac{\text{mean (E.M.F.)}^2}{\text{resistance}}$$

$$= \text{R.M.S. value of E.M.F.} \times \frac{\text{R.M.S. value of E.M.F.}}{\text{resistance}},$$

$$= \text{R.M.S. value of E.M.F.} \times \text{R.M.S. value of current.}$$

We thus arrive at the following important result:

In a circuit of negligible inductance, the mean power, in watts, is equal to the product of the E.M.F. in volts into the current in amperes.

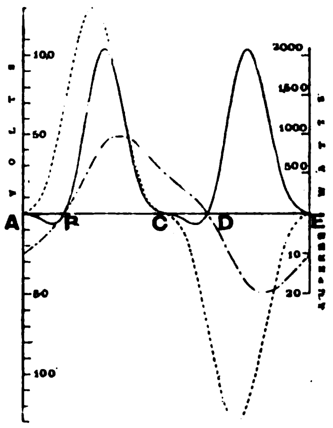

FIG. 48.

The student will notice that this result is true for waves *of any shape*, as we have made no assumption regarding the wave shape in the above reasoning.

We may, therefore, determine the power in any *non-inductive* part of a circuit by measuring the P.D. and current, and taking the product of these two quantities.

59. The above simple rule ceases to hold when the circuit is an inductive one. If the E.M.F. and current waves are known, we can easily determine the mean power by the method already explained for finding the mean value of an E.M.F. or current wave. We have merely to divide a half-period into a convenient number of equal parts, and determine the power corresponding to the middle point of each division. By adding the values so obtained, and then dividing by the number of divisions, we obtain the mean power in the circuit.

The difficulty which arises in the determination of the power in an inductive circuit is due to the fact that in such a circuit we have, as has been already explained, two E.M.F.'s, the impressed E.M.F. and the induced E.M.F. (Art. 37). During a certain fraction of every half-period, the induced E.M.F. is greater than the impressed E.M.F., so that *the current flows against the impressed E.M.F.* If the student will refer to Fig. 29, he will notice that the impressed E.M.F. is, during a certain fraction of each half-period, of opposite sign to the current. Now in accordance with the principle explained in Art. 27, an E.M.F. which is opposed to the current in a circuit becomes a *sink* of energy. During a certain fraction of the half-period, therefore, the source of alternating E.M.F. *absorbs* energy.

Digitized by Google

This means that an alternator working on an inductive load acts as a *generator* during one part of every half-period, and as a *motor* during the remaining part. We thus have a periodic storage and discharge of energy in the circuit, the energy being temporarily stored in the form of a magnetic field surrounding the circuit (Art. 32).

In Fig. 48 the dotted curve is an E.M.F. curve,* and the chain-dotted curve shows the corresponding current curve in a circuit of resistance 3·95 ohms and inductance ·00786 henry, the periodicity being 80 ⁀‿ per second. The full-line curve is the *power* curve, and shows the manner in which the power fluctuates during a period. Between the points A and B, and C and D, the impressed E.M.F. and the current are of *opposite* sign, hence the power is *negative.* Between B and C, and D and E, they are of the *same* sign, hence the power is positive. If at any instant the power is *positive*, then this means that the source of alternating E.M.F. is acting as a *generator*, and supplying energy to the circuit; if, on the other hand, the power is *negative*, then the source of alternating E.M.F. behaves as a *motor*, receiving energy from the circuit.

In order to determine the mean power in the circuit we divide the half-period, A C, into 10 equal parts, and erect perpendiculars to the axis of time at the middle point of each division. The lengths of these perpendiculars we find to be

$$-20, \ -100, \ -100, \ +300, \ +1{,}300, \ +2{,}020, \ +1{,}800, \ +900, \ +250, \ +20.$$

Their sum is 6,370, and hence the mean power is $\frac{6{,}370}{10} = 637$ watts.

Using the method explained in Art. 53 for determining the R.M.S. value of a periodic function, we find that in the present case the R.M.S. value of the E.M.F. is 73·8 volts, while that of the current is 12·7 amperes. The product of the volts and amperes is therefore $73{\cdot}8 \times 12{\cdot}7 = 937$. But this product, as we have just seen, does *not* represent the true power in the circuit, and is sometimes spoken of as the *apparent watts* in the circuit. The ratio between the *true watts* and the *apparent watts* is termed the *power factor*, and this ratio is a very important quantity from a practical point of view. In the case under consideration, the power factor is $\frac{637}{937} = {\cdot}68$.

60. When the circuit is non-inductive, the apparent watts equal the true watts (Art. 58), so that the power factor is unity. It is in all cases desirable to have the power factor as large as possible, for an increase in the power factor always means an increase in the economy of working. Thus, let us suppose that a certain inductive load is worked by two alternators of the same output, the power factor being ½, and the current supplied by each alternator being the full-load current. Now, although each alternator is supplying its maximum *current*, it is only running at half-load, and so is the engine driving it. Let us contrast this state of affairs with that in which the power factor is unity. Supposing that the P.D. and load are the same in both cases, it follows that only half the current will be required in the second case. Hence a single alternator running at full load will be sufficient, and it is obviously more economical to run one alternator at full load than two alternators at half-load.

There are also other advantages of working with a high power factor. For a given load, the current varies inversely as the power factor. Hence, the rate at which energy is dissipated by heating of the circuit will vary inversely as the *square* of the power factor. Also, the drop of potential along a given line will vary inversely as the power factor. For both these reasons it is desirable to maintain the power factor as high as possible.

A bank of incandescent lamps, or of closed magnetic circuit transformers *fully loaded*, constitutes an arrangement for which the power factor is practically unity. On the other hand, a load of closed magnetic circuit transformers with open secondaries, of open magnetic circuit transformers (whether loaded or not), and of alternate-current motors, furnish examples of cases in which the power factor may be very small. The power factor may be increased by the use of condensers. This effect will be discussed later on.

* The E.M.F. in this example is represented by the two simple harmonic terms $100 \sin pt - 30 \sin 3pt$.

(To be continued.)

NOTES ON ELECTRIC LIGHT IN SEA-GOING VESSELS.

BY E. CRAIG-BROWN.

For one who has not actually had experience in the practical running of electric installations both on land and at sea it would be difficult to properly realise the enormous difference between the two practices. An electrician who had learned his calling in one of the magnificent central stations now to be found in nearly all our towns of note, or who had had charge of private installations, however complicated or troublesome, would find himself at sea in more than one sense if suddenly asked to run the electric lighting plant of one of our large ocean-going steamers. Besides having to face many difficulties entirely new to him, he would be led sadly astray if he attempted to cure with his shore-going remedies troubles that he fancied he recognised from his shore-going experience. They might be the same troubles to all outward appearance, but as often as not arising from widely different causes.

And why is all this difference? Does the engine not get steam from the boiler, the dynamo energy from the engine, the leads current from the dynamo, and the lamps from the leads? These are general questions, and to them the answer is, of course, "Yes," but if we begin to examine the *details* of working we must qualify that answer. The engine certainly gets steam from the boiler, but at sea the electrician as a rule has nothing to do with that boiler. He must take his steam as he gets it—*i.e.*, as made for the main engines.

Again, "Does the dynamo not get energy from the engines?" "Well, not always." In the latest marine plants where direct-driven machines are installed, of course the dynamo gets what the engine can give, but in many engine-rooms the old friction gears are still to be seen.

The following may explain what is meant: *Scene*, engine room of deep-sea steamer; *time*, say, 10.30 p.m. All going sweetly, main engines running well, engineers in good humour. Electric department satisfactory, voltage good, electrician also in good humour. *Group* consisting of the engineer on watch, the boilermaker, and the electrician spinning yarns under the lamp near the starting gear. Ghost-like "panee-wallahs" flitting about with oilcans and handfuls of waste amongst the plunging rods and levers overhead. Suddenly, in middle of boilermaker's best story, "Cri-i-i-n-n-n-n-n-g!!" goes the telegraph, "stop." "Cri-i-i-n-n-n-n-g!" again, "half astern." A second's pause; then the boilermaker is running up the ladder with a spanner to stand by that troublesome reversing gear on the H.P. eccentrics; the engineer is unlocking the levers, and the electrician is replying to the bridge by the telegraph. That done, he rushes to his machines. The "fourth" has pulled over the levers and is hanging on to one of them, the little starting engine has begun to work, spitting, knocking, and sticking. A little help to "the wheel" by hand, and it is flying round, the oil coming off its rim tangentially and going on to the faces of the electrician's friction pulleys. The main engines slow down, and the extra steam thus left in the boilers sends up the pressure. The dynamos whirr, up goes the voltage till the lamps look like melting, and at the same time up goes the electrician's hand to the regulating valve. Too late; what with the sudden increase of speed and the oil from the starting wheel the friction is overcome and the pulleys slip. Down go the lights, up goes the smell of burning oil and resin, and the dynamo engine races as if it would knock itself in pieces. In vain does the electrician apply his best pocket-handkerchief to the pulley faces; the initial friction having been overcome nothing short of slowing down and the judicious application of powdered chalk to their faces will cause the pulleys to "grip" again.

Digitized by Google

By this time the cause of the sudden stoppage becomes known. [Run into a Chinese fishing fleet off Fu-chow-fu, or something of that sort.] The telegraph signals "slow a-head," and the chief engineer is anxious to know "What's wrang wi' they —— machines again, as the captain has been speerin' at him aboot the lichts?"

To continue, "Does the dynamo not supply the leads with current?" "Well, yes, in a way. The positive lead gets all that doesn't leak from the brush rocker into the hull of the ship." You see (unless our electrician is lucky and has one of these slow-speed drum armatures to manage) the motion of the ship has to overcome a very considerable amount of gyrostatic action in the armature. The bearings, therefore, are subjected to heavy work, and if they are lined with white metal he gets rather anxious about them on a rough night, so anxious that sooner than see them running out at the end of the spindle from overheating, he is lavish with the oil. As their temperature still increases, however, he borrows some snow from the refrigerator man and applies it to the outside of the plummer blocks. It *may* keep the bearings from getting too hot, but it certainly *does* run everywhere when it melts, even over his vulcanite washers, and leakage follows as a matter of course. Speaking of rough nights, if he is not used to them, he may have occasion to go on deck several times "to see if there is much phosphorescence in the sea." During his absence the machines are left more or less to themselves, as the engineer on watch may not be conversant with dynamos.

Now for the leads themselves. There are three systems—viz.: (1) double, (2) single, and (3) concentric.

(1) The double leads are on the same principle as those on shore—*i.e.*, one positive and one negative.

(2) The single system is the oldest, as it is the one that would naturally occur to a telegraph electrician. The negative wire is put to "earth" on the nearest bulkhead. This is better than merely taking the insulating washer out of the negative brush-holder. Similarly the return wires from each lamp have to go to "earth." This, of course, entails much drilling and tapping of ⅜in. holes in plates for terminal screws.

(3) The concentric system is used chiefly in the Royal Navy, and where expense is not the chief consideration it is undoubtedly the best. Jointing requires a trifle more skill and patience than in the other systems. Making a joint ashore is one thing, at sea quite another. Picture the electrician trying to stand on a camp stool in a cramped and dark corner of an alleyway with a rapidly cooling solder bolt in one hand and a stick of solder in the other. The ship is pitching and rolling, so he has to steady himself by pressing his head against the ceiling. Temperature, say, 90 something, and vision imperfect, owing to excessive and continual perspiration. The most angelic temper sometimes gives way in such circumstances. The following table, though by no means exhaustive, gives a few of the principal arguments for and against the three systems:

DOUBLE.

Advantages.

1. Less tapping of plates required.
2. Fewer sources of short-circuit and leakage.
3. Less likely to affect ship's compass
4. Danger of shocks to passengers a minimum.

Disadvantages.

1. More drilling of plates required.
2. Greater initial expense.
3. Chances of rupture by straining of ship or corrosion by sea-water doubled
4. More time and trouble to alter or repair.
5. Double casing necessary and therefore more space occupied.
6. Double cut-out fuses almost a necessity.
7. Not impervious to damp.

SINGLE.

Advantages.

1. Simplicity and cheapness of installation.
2. Single casing used, and therefore greater economy of space.
3. Repairs simple and faults easier to locate.
4. Fewer and simpler cut-out fuses required.

Disadvantages.

1. Tapping plates for earths.
2. Danger of shock from faulty or damp switches.
3. Chances of short-circuit and leakage all along leads.
4. Chance of deflecting ship's compass.
5. Not impervious to damp.

CONCENTRIC.

Advantages

1. Casing only required where there is a chance of rough usage—*e.g.*, when second-class accommodation is utilised as cargo space.
2. Great economy of space.
3. Less unsightly than other systems.
4. Short-circuit and leakage a minimum.
5. Less danger to compass.
6. Danger of shock a minimum.
7. Impervious to damp

Disadvantages.

1. Initial expense.
2. Greater skill necessary for repairs.
3. Liable to damage by indentation.

With reference to disadvantage No. 2 in the single system, the pressures commonly used on board ships are never high enough to do anybody harm, but a timid person who tries to turn on a switch while standing in a bath may be somewhat startled if the splashes and general dampness of the average ablution room have got behind the porcelain cover. Of course all leads, whatever be the system, must be easily got at along their entire length, while switches and fuses must be located in convenient places. In saloons, leads are often run behind panelling. When this is done, the panels must be so constructed that they can be easily removed and replaced. Some skill and experience are required to run leads successfully in a ship. Casing cannot be nailed up at random and wires carried through walls as on shore. Laborious drilling and tapping of holes in bulkheads is necessary, so the problem is to run the leads efficiently with the minimum number of holes.

There should always be two (or more) entirely separate circuits in a ship, one for each dynamo; and one lamp at least in each room should be on a different circuit from the rest, so that should one machine fail suddenly the room may not be left in perfect darkness. Thus, from sunset to "lights out" both machines are running, and all the lamps may be burning. At "lights out" the day circuit is shut down and the night circuit goes on till daylight. In a passenger vessel the following would roughly be the arrangement: *Day circuit*—saloons, smoking-rooms, alleyways, etc. *Night circuit*—one or two lamps in saloon, ditto in alleyways, engine-room and stokehole, cabins, quarters, cargo lamps, etc.

The switchboard in the engine-room should allow of either unit running either or both circuits. As the night circuit is on much longer than the day, it should be run alternately from one or other of the units so that the work is not thrown too heavily on one machine.

Vessels fitted with a searchlight projector should have the circuits arranged so that when it is in use one unit is entirely at its disposal and both circuits are on the other. To reduce the load on the machine that is thus running both circuits, all lamps that can be reasonably done without should be disconnected for the time being. These arrangements are, of course, for vessels in which the searchlight is seldom used, otherwise a separate and distinct installation should be fitted for the projector, independent of the other machines and circuits altogether. Of course, in any case the projector leads would run direct from the switchboard to the instrument, untapped and independent of any others. *They* should never be on the single-wire system, and the fuses should be as strong as the safety of the dynamo will allow. With all hand-regulated projectors the resistance of the circuit is liable to sudden and frequent variations which test fuses to their utmost and render necessary the constant services of a dynamo attendant.

With reference to lamps, the spherical, dimmed-glass globe hanging from three arms projecting round the end of a pendant or bracket fixture is an excellent arrangement, and would be hard to beat for simplicity and convenience. The bayonet lamp socket is the best. That kind of lamp which is attached to two spiral springs by little platinum loops is too great a temptation for the curious. Their zeal for experiment leads them to put the blade of a knife across the terminals, and then, if the lamp fuse does not go, the branch one very likely will, and the place is suddenly darkened. One improvement suggests itself, however, on the metalwork of the fixture. Instead of having it of

Digitized by Google

brass, polished or lacquered as at present, have it rough cast or bronzed, for the following reason: In a ship, from the captain downwards, there is a universal and incontrollable mania for polishing brass. As long as it is confined to handrails, binnacles, lubricators, etc., it is to be encouraged, but when the chief steward casts his eagle eye about the saloon and sends a Portuguese waiter to polish the lamps, it is time to draw the line. The waiter, armed with polishing paste and a cloth, mounts the table or a camp stool and steadies himself by hanging on to the lamp with one hand, while he rubs it vigorously with the other. Every time the ship rolls or pitches a large part of his weight comes on to the bracket, and it is not long before it ceases to have any claim to be called a "fixture." Once loosened, every movement of the ship tends to increase the mischief. Now, if the chief steward saw that these fittings were not meant to be polished, he would leave them alone, and much trouble and annoyance would be saved all round.

Vibration is another source of trouble, inasmuch as the incandescent filaments often shake till they touch the glass of the lamp bulb. This cracks the bulb, and admits air, if it does not at once sever the filament. This may often be avoided by turning the socket so that the plane of the loop is coincident with that of the arc through which the filament tends to vibrate (Fig. 1). In this illustration the arc through which the filaments tend to vibrate is shown and marked A B. The position on the left is the best, as the filament is more stable, while the position of the filament shown on the right is bad.

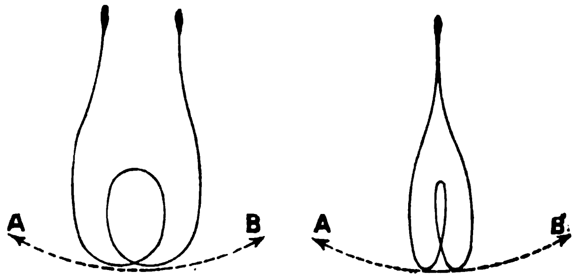

FIG. 1.

Wherever dual control exists there is also a mine of provocation. This is exemplified at sea, not only by the steward's desire to polish the electrician's lamp fittings, but also by the delight quartermasters have in rendering useless the flexible cable connections on cargo lamps. Perhaps the fault lies as much with the connections as with the quartermasters. As a rule they are made only to conduct electricity, not to take any tensile stress. This is a mistake. The quartermaster screws the terminal on to the socket all right, as he has been taught, but he adds a good sailor-like tug to see if it is firm. This ruptures the flexible strands and out goes the cluster. Failing a better designed type of terminal screw, a strong light line should be rigged alongside the cable to take the strain, the cable to be looped up on to it as may be seen overhead in streets where a strong steel wire takes the weight of a heavy conductor.

On board ship space is limited, and therefore must be economised. This tends to cramping. Engines and dynamos are stowed away in odd corners, the trouble of cleaning and repairing being thus greatly increased. An electrician used to a spacious central station on shore with everything up-to-date misses a hundred and one little conveniences, and finds them replaced by worries he never dreamed of before. Refitting crankhead brasses, inspecting pistons, and the like, are operations requiring skill and patience in any circumstances. When they have to be carried out in a hot, dark, stuffy, and dirty corner, somewhere in the bottom of a marine engine-room, only one who has actually experienced them can realise what a lot of work they entail. Yet at sea there must be no scamping or shirking of work: the safety of the ship may rest on the merest detail. It is very pleasant to lie in an easy-chair on the hurricane deck when off watch, but it is absolutely necessary to finish your engine-room work first.

THE RECENT TELEPHONE CONVENTION IN AMERICA.*

BY FRED DE LAND.

It was a happy thought that resulted in the election of Judge Barstow as the presiding officer of the convention, for the honourable judge is a prince among optimists, and a firm believer in the gospel of good cheer. Thus, no amount of croaking could entirely dispel that hearty cheerfulness that permeated every session. To be sure, now and then the discussions were tinged with melancholy, and on the whole the proceedings were of a depressing character, but the judge was as bland as the honey of Hyblea. What matter if Waukesha had "ceased business and sold the plant for a nominal sum, sufficient to cover outstanding indebtedness, leaving the original investment a total loss"; that La Grange had gladly laid down its burden and pocketed the loss; that Selma's doors had been slammed in the face of an ungrateful public who could now pay the higher rates of the Bell Company, simply because they desired some return on an investment that ought to have been given freely from a sense of pride in a home institution? To be sure, the officials admitted that the prices charged and the service rendered were so unsatisfactory that the service had to be abandoned, but their opinion was naturally biassed. Or that St. Joe was wondering how so much money could be for ever lost so quickly, though the local Press laid the blame on "unsatisfactory service—want of out-of-town connections, inferior appliances to the Bell Company, and a rate too low to enable them to attempt a comprehensive service." Suppose the competing telephone plant at Nevada that cost £400 was sold for £30, and that the Pittsburg plant on which over £600 was invested was disposed of under the hammer for £120. Did not the smooth promoter get away with his commission? What if the courts have ordered the notorious Harrison Topeka telephone plant to be sold to satisfy judgments aggregating £6,000. Is there not an abundance of wealth yet remaining in Kansas yearning for just such profitable investment? And who can locate a soft mark quite so quickly as the slick telephone promoter who was the understudy of Dusty Rhoades but a brief space agone? Why should the learned judge care if the Florida long-distance telephone system was disposed of for £30 at Orlanda by a brutal sheriff clothed with a little brief authority? or that the Ypsilanti automatic telephone exchange had been discontinued? The judge was content to look upon the bright side of life, even if 12 members had been side-tracked by the sheriff or for some similar reason since the last meeting, for he well knew that though the hot sun was now roasting the members, yet with the opening of the gates of night would come the stars, and the cooling breeze, and the refreshing sleep, and in that land of dreams that yet may prove to be the real world there is no worry over doomed financial ventures voluntarily assumed; so why worry?

And having called the meeting to order, the judge declared the convention of independent telephone companies open, and directed the calling of the roll. This being done, the secretary reported a gain of 22 new members and a loss of 12 members. As the names of these 12 delinquent members were called, only harsh and unpleasant comments were heard on every side, due, apparently, to no other cause than that some among these ill-fated 12 had allowed an uninvited and ill-bred deputy sheriff to enter their respective exchanges and levy on the entire plant, merely to satisfy claims for small amounts of filthy lucre. But the judge rapped for order, and said the remarks were uncalled for. "We should learn to bear easily the misfortunes of our friends, and, with Euripides, remember that that man is wise among us, and hath understanding of things divine, who hath nobly agreed with necessity."

After the various committee reports had been read and disposed of, the meeting was declared open for the discussion of special topics germane to the best interests of the association, and the chair urged the members to participate in a full and spontaneous expression of opinion on the

* From *Electrical Engineering*.

Digitized by Google

rumoured consolidation of all the property interests of the principal Bell licensees and their absorption by the parent company, thus doing away with the royalty fee and effecting a marked reduction in the operating expenses, enabling them the better to meet competition. The chair also desired that the sentiment of the association be placed on record regarding the attitude of the manufacturing telephone companies towards the operating telephone companies. He did not believe that the manufacturing companies were standing up as manfully as they had agreed to, and there was little doubt in his mind that the independent exchanges would have to fight their own battles, while the manufacturing companies exhausted their energy in petty internal squabbles. Thus he believed that the association was not interested so much in what the telephone manufacturing companies were going to do, as whom; for experience had shown how honest they could be when certain of being detected. Nor would he advise any member to lean on any telephone manufacturer for legal assistance in defending the suits the Bell Company would certainly institute. For, basing his opinion on personal observation and the published statements in the electrical Press, the chair felt confident that the affairs of these manufacturing companies were in such shape that they could immediately close down or assign in the event of the United States Supreme Court again deciding in favour of the Bell interests. Thus, it is really the part of wisdom to look upon the bond and the guarantee of telephone manufacturers as absolutely valueless, for the Court proceedings already taken show that some, if not all, "are pecuniarily irresponsible and unable to respond to a decree for damages in favour of the complainant in this suit."

The question was asked by one of the members whether there was any reliable information on record regarding the financial standing of the Home Telephone Company claiming several thousand subscribers in many cities, according to the very reliable electrical journals. The secretary replied by reading extracts from a report on the Committee on Telephones for the district of Columbia, on Bill S. 2,498, showing a claim on the part of the promoter of having secured 3,400 subscribers in the district of Columbia at a rate of £8 and £6. 8s., taken from "the portion of the business people of the city who have not been so successful in life, and who have no particular use for the more expensive metallic connection." "We expect to serve people who cannot quite afford to use telephones unless this company is chartered." The gist of the testimony showing that "if the franchise were granted to-day, two years from now would not see 200 commercially working Home telephones in the district of Columbia, if any." The secretary also read extracts from the Cleveland *Plain Dealer* and the Cleveland *Leader*, of May 12, 1895, showing that the Home Company "has no serious intention at present of going ahead with its project." Yet in each city they were successful in disposing of privileges, stock, etc., at good prices. These comments reminded the president of the story of the practical politician who boasted that he had made £50,000 in the last two years, "but I worked for it." "Of course you did," was the reply, "but whom did you work?"

Mayor Pingree's Detroit Telephone Company, that is to be operated for 50 per cent. less than the present exchange, next came in for a fair share of criticism for masterly inactivity, and in closing this discussion later on, the chair remarked that the good mayor's comments on the absence of proper protection for the rights of the people were worthy of the able politician who said that all knowledge which does not increase a man's virtue makes him the more dangerous. And he recalled a brief conversation between two politicians accidentally overheard in one of the lower wards in his city: "You look done up, Chimmy. Is it worryin' yuh to make all those reform speeches to the people of your ward?" "It isn't the reform speeches, Tim, it's the work of gettin' the boys to understand how I don't mean 'em, that's worryin' me." The deduction drawn from the printed statements issued by this Detroit Company is that with an average telephone rental of £6. 16s. a year for 5,000 telephones, 10 per cent. dividends can be paid on £120,000 in capital stock, and 6 per cent. on £80,000 in bonds. And all purchasers of stock would be given an equal amount of interest-bearing bonds. In other words, this "reform" organisation would not pattern after the highly improper methods adopted by the grasping corporations so heartily denounced by his honour, "the friend of the people," but would add the water before winning success. In the prospectus issued by the Pingree-Detroit Company earnings and expenses are itemised, thus enabling a comparison to be made with the present expense account of the Bell Company in Detroit, having 4,300 subscribers. Female switchboard operators, Pingree Company, 60 at £1 a week, or £3,000 annually; Bell Company, 107, averaging 24s. per week, or £6,677 annually. The Pingree Company will have ten linemen and three labourers at an annual outlay of £1,500, while the Bell Company finds it necessary to keep 56 linemen and inspectors continually employed at an expense of £6,720. Batteries have to be renewed every few weeks, this item aggregating £2,000 annually for the Bell Company, yet the Pingree Company make no provision for this very necessary expenditure. For new material and repairs to Bell circuits nearly £5,000 are expended annually, yet the Pingree prospectus makes no allowance for this, nor for depreciation, though in 1893 the Bell Company replaced a switchboard that cost £10,800 with one that cost £24,800 and had previously discarded boards costing over £12,000. Yet the Pingree Company add: "And on every additional 1,000 telephones used, the net profit per annum would be £5,000, the ratio of profit being higher as subscribers increase."

The member from Pittsburg suggested that the Pingree Company should secure the services of the bland promoter who has been weaving his meshes about the gullible citizens of Kansas City, as he possessed the ability of operating an exchange of 3,000 telephones at a total expense covering all items averaging but £2. 8s. per telephone, while the Pingree Company allowed the extravagant sum of £3. 1s. 3d. per instrument. To be sure, the Bell Company claims that it costs them about £12 an instrument to operate their exchange, but who believes the fairy tales of successful dividend-paying corporations? Then this Kansas City weaver offers his telephones at only £6. 8s. a year, and his circular clearly demonstrates that if only 3,000 telephones are rented at this figure the annual income will be £19,200, the total annual expense £7,200, leaving the handsome net income of £12,000, or a return of 12 per cent. on an investment of £100,000. But for fear that the holders of this stock may become proud in spirit, the weaver limits the number of shares that any one person should hold to 10 shares of £20 each.

Comment was also made on the promised competition that has failed to materialise in Chicago, Philadelphia, St. Louis, and other large cities, and to the feeling of pride that must permeate the bosoms of Messrs. Clarkson, Egan, Tracy, Aldrich, Porter et al., when they gaze upon all that has been accomplished.

Incidentally, the chair remarked that there was ample legal talent both within and without the association ready for sacrifice in fighting this gigantic monopoly—for a consideration, but that he had fully made up his mind that the only safe course to pursue, when the United States Supreme Court delivered its opinion sustaining the validity of the Berliner patent, was to surrender and have his loss as small as possible, unless in the meantime he could find some good-natured relative on whom he could unload his holdings in the independent exchanges.

Here the member from Oskaloosa interrupted the president's remarks by asking if he could name an actual independent exchange; there were plenty of dependent exchanges dependent on the holders of overdue notes and mortgages; but an independent competing exchange? Impossible! One of the exchanges in Iowa was so anxious to be absorbed by the Bell or any other company without money and without price that its beseeching attitude reminded him of the tramp's reply. Weary Willie had entered the yard with the firm intention of disabling all competition, but by a masterly retreat he had scaled the fence just in time to escape the fangs of a savage bulldog: "Madam, I did intend to demand something to eat, but all I ask now is that, in the interests of humanity, you'll feed that dog."

Digitized by Google

The next question that came up for discussion was the advisability of erecting toll lines. One of the members appeared bent on forcing each company to bear its share of an assessment that would enable interconnecting lines to be built and thus afford subscribers in one exchange full communication with the subscribers in any other exchange in the state. But he talked so long and digressed so widely that when he finally subsided someone was cruel enough to intimate that there are a great many ginger-pop people in the world. After they have been uncorked for a few minutes they get to be dreadfully flat.

Mr. Cleveland doubted the wisdom of erecting many toll lines "until we have had more experience in this business. If we do we shall probably have good cause to regret the outlay. For few toll lines have proved to be a profitable investment, either in the East or the West. Take the lines that connect the small outlying village exchanges with any large city, and the income rarely equals the operating expenses, while the deficit—to make good the cost of maintenance and the fixed charges—must come out of the income of the city plant which creates and maintains a toll line and exchange for the convenience and benefit of its city patrons, rather than from any expected profit that would accrue from village conversations. Rarely will the public pay more than ½d. a mile for short distances of 50 miles or less, and ¼d. for distances exceeding 50 miles, and as an average of only five conversations per hour can be held over any ordinary toll line, the income never justifies the outlay save from the standpoint of favouring the subscribers of the large exchange."

A spirited discussion followed, in which nearly every member participated, but it was soon evident that some prearranged plan existed for forcing the association to endorse a movement in favour of toll lines. The minority protested against any action that necessitated further expenditures of moneys. Toll lines were necessarily expensive to build properly, as well as difficult to maintain in good working order in this section so often visited by severe storms, while it was doubtful if the receipts would ever equal the cost of operating the lines; and as not one shilling of legitimate profit had yet been secured from any investment in these small independent exchanges, any motion to increase the investment until a dividend had been declared would meet with determined resistance. Even with their more profitable rates the Bell Companies did not dream of general toll lines for several years after the principal exchanges had been established, and only since August 1 has it been possible to talk direct from Davenport to eastern points over the long-distance trunk lines.

Mr. Cleveland said that he fully appreciated the great value to a local exchange of the right of way for transmission of messages over trunk lines, and he felt that in the near future some concerted action that might bring about interstate connections would be not only desirable but absolutely essential to preserve the integrity of the capital already invested. But this was not the time nor the place to adopt coercive measures. No one appreciated more fully than he did the great value of the telephone as a time-saver to business men, and he had heard of many instances of men travelling by rail to Chicago and then using the long-distance lines to close some important deal in Boston or New York, or some Eastern city. But these long-distance trunk lines were owned by a separate company, and built and maintained by capital invested independently of any investment in the local exchange. No doubt an independent long-distance company might be formed, but he did not care to invest any money in such an enterprise. To build a pole line properly and string two wires for one complete metallic circuit would cost £80 to £90 a mile; additional circuits could then be added from time to time as the traffic justified, at comparatively small expense. Yet, he understood that toll lines had been built for £50 a mile, and rebuilt after the first heavy storm. Even the lines in the city of Madison, the headquarters of a branch of promoters, could a tale unfold were they inclined to be talkative.

Mr. Bartin defended the other side of the question by saying that experience had taught some very good Wisconsin people that profits can only be realised when capital is invested in a productive enterprise operating more fully, more satisfactorily, and at less cost than existing competition, and more especially is this true of public or semi-public service plants, where the ultimate profitableness of the investment is so largely dependent on the general acceptance of the service supplied. This was well illustrated in the case of the Waukesha telephone exchange. No Wisconsin town enjoys so many advantages, so many well-to-do, progressive, and public-spirited citizens, who never hesitate to make any investment that will aid in building up their town, and make it still more famous, not only for its beautiful surroundings and its health-restoring mineral waters, but for the public conveniences afforded the citizens. Thus, when a new telephone exchange was proposed ample capital was quickly forthcoming, and in a short time an excellent exchange was in operation, with a large number of subscribers, and there was every indication of it being a prosperous undertaking. But after the third or fourth month the receipts began to drop off, and gradually one subscriber after another relinquished the service until the plant was sold for a sum that merely covered the current bills, leaving the original investment a total loss. The explanation is easily given. It was not so much a question of the inferiority of the instruments or the indifferent service furnished, as it was the absence of all toll-line connections. Now, the majority of the well-to-do residents of Waukesha have their places of business in Milwaukee, Chicago, or in one of the towns in the valley, and necessarily must have telephonic communication that is at all times available to those points. Thus, when they found that the new telephone circuits were limited to the subscribers within the town, and that to have constant telephone facilities with outside places it was necessary to also subscribe to a Bell instrument, they naturally came to the conclusion that a second telephone was of no real value and quickly dropped it. And thus, while the new exchange had more subscribers than the old Bell Company at the start, the new company could not give the service demanded, and thus had to close its doors. And Mr. Bartin believed this would be the fate of every exchange represented in this convention, unless they joined in the building of interconnecting lines that would enable them to give the class of service any customer might desire.

The report of secretary E. M. Hopkins, of the Board of Trade, Saginaw, Michigan, who was commissioned to investigate and report upon the advisability of establishing a competing telephone exchange in Saginaw City and the Valley, came up for consideration, and was severely criticised because of his adverse decision. Mr. Hopkins reported that "There is one conclusion you quickly reach, and that is that someone has been lying about the telephone business. You cannot by any possible reasoning reconcile the figures put forth by telephone company promoters and the Bell people. They are as far apart as daylight and darkness. . . . Judge Gages states that each individual subscriber to the stock of a telephone company is individually liable for all material and labour used." And his recommendation was adverse to investing any capital in a competing telephone exchange "until the decision of the Supreme Court is had in October."

[The foregoing description will convey to our readers some idea of the present state of the telephone industry in America.—Ed. *E. E.*].

Wedding.—The marriage of Mr. Harold Faraday Proctor, second son of Mr. Barnard S. Proctor, of Newcastle-on-Tyne, and electrical engineer to the Bristol Corporation, and Miss Amy Peckett, youngest daughter of the late Mr. Thomas Peckett, of Hyde Lodge, Durdham Down, took place at the parish church of Westbury-on-Trym. The bride was given away by her brother, and her two sisters were the bridesmaids. Among the wedding presents was one from the members of the Bristol Electrical Committee, who presented Mr. Proctor with a handsome silver tea and coffee service, suitably engraved. The staff at the electric lighting works gave a silver salver, and the employés at the works a fine engraving. The employés at Messrs. Peckett's engine works, St. George, presented a handsome timepiece.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

OPINIONS v. FACTS.

The differences of opinion between experts are likely to last until we reach the happy time when all men will be exactly equal, and hence expert advice will not be required. We hold that these differences of opinion are in many cases incentives to improvement; but that when they become active weapons for opposing progress, expert advice is worse than useless. Thus, for years in England we have had a keen fight between experts as to the ultimate advantages of the alternate and direct current systems of distribution. A few engineers have taken the broad-sided view of the matter, and have used both systems as the character of the town to be lighted demanded. Others, of whom the manufacturing side claim a large proportion, have taken a more party view of the matter, and certain small and compact towns have been equipped with high-tension alternating-current machinery in consequence. The difference between one shift of men and three then makes itself strongly felt. As a result the expenses of running have swamped the income, and the undertakings have not been financially successful. The comparison between the two systems now that high-voltage lamps have been introduced needs further consideration, and the use of high-tension distribution with rotary transformers has also helped the direct currents at periods of heavy load. The high-tension direct-current machinery, as used in several towns in England, equalises to a large extent the difference between the two systems. Still, opinions are free, but we do not like to see opinions hinder progress. After a certain company, for instance, has been working at a problem of town lighting for some time and has got some way towards commencing work, we do not believe in condemning their plans unless there is no chance of their success in practice. The electric lighting of Calcutta is thus jeopardised, as will be seen from the reprint of a contemporary elsewhere in our columns. As will be remembered by our readers, the question of the cables to be used was also well taken up by the same paper some few weeks ago. We see no reason why the company in question should not make the lighting of Calcutta a financial and electrical success with distributon on the low-tension system, with perhaps high-voltage distribution to the sub-stations, although we would agree with our contemporary that the alternate-current system might cost less in the first instance. Still, the comparisons drawn between the two are not complete, and the lack of several essential facts detracts from the value of the criticism. For instance, the comparison between the loss in the mains is given, and, as is well known, the low-tension system works at its worst efficiency at full load. Hence, as compared with the alternate-current system at full load, it would seem to be quite out of the running. Yet the other side of the question needs attention, and at light loads the positions are reversed. The transformer loss, of which we find no mention in the paper before us, reduces the efficiency of the alternating-current distribution to a low figure at such periods. In other words, the low-tension losses are large at a paying load, when

Digitized by Google

these can be afforded. The fact of the increased cost of coal per unit sold in the alternate-current stations is mainly due to the losses in distribution, as the efficiency of the generators does not differ much. Another point in the report that strikes us as bearing hard on the low tension is the statement that "the alternate current affords the most remarkable facilities for the transmission and distribution of energy in the form of motive power." This is perfectly true, but the low-tension system affords even more remarkable facilities. Also, if a three-wire two hundred and twenty-volt service were adopted, as it can well be in the case before us, the facilities for supplying the tramway service would be most valuable. This fact alone, if there are fair prospects of traction work, should be a strong point in favour of the project now before the officials of the city of Calcutta. We wish the promoters every success, and trust that the features of the scheme other than technical to which our contemporary finds objection may be successfully negotiated. It is quite time that an important city like Calcutta should reap the benefit of the electric light, and we trust that differences of opinion may not prevent this desirable end.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LEEDS TRAMWAY—CLERK OF WORKS.

Sir,—I read with considerable interest—as might be expected—your leading article on the above matter in last week's issue of the *Electrical Engineer*: and may now perhaps be allowed to express—without undue impropriety—my agreement with much that you say, as well as with the fundamental position taken therein.

When, however, you say that the applicants were "given to understand that the gentleman who should be chosen to act as clerk of the works during construction would most likely be appointed engineer afterwards," I would like to know whether your information was official in this respect or not. My own experience does not bear out the statement, except in so far as might be gathered from the fact publicly stated beforehand that the work was expected to be done in six months: for obviously a man of good professional standing would hardly expect to go to Leeds for a few months only.

Seeing that my name has appeared in connection with the post, I would like to say that (as my friends would probably guess) I was *not* the applicant who offered to undertake the work for the magnificent salary of 45s. weekly—that is, 15s. a week more than the Leeds Corporation pays to some of the tramcar drivers! — Yours, etc.,

Frank B. Lea.

DEAD-WEIGHT IN TRAMCARS—IS IT PROFITABLE OR PRACTICABLE TO REDUCE IT?

We hear much in these days of the wonderful load a bicycle carries in proportion to its weight, says the American *Street Railway Review*, and it is hinted often that cars weigh much more than they should in proportion to the loads they are expected to carry. Indeed, *Locomotive Engineering* remarks that "a study of the bicycle might prove a profitable pastime for the designers of railroad rolling-stock," and says, "the trend of car designers is to increase the proportion of dead-weight to paying load." This is more noticeable in steam-road practice than in street railway work, for although the weight of street cars has increased, it has been due more to the addition of electric motors and greater seating capacity than to any great increase of weight of car body per passenger. However, the weight of cars and motors is very great in proportion to the load they are ordinarily expected to carry, and it certainly is not out of place to investigate the subject a little.

In considering a matter of this kind there are two questions that immediately come up. First, is it mechanically possible to reduce the weight? Second, if it is possible, will it pay? As to whether it is mechanically possible there is not much doubt but that there might be some reduction in weight if roads were willing to pay for it. How much, no one seems inclined at the present day to state. That is something which could only be decided by long trial and experiment Before spending money in trying to answer the first question, the second question as to whether it might pay must be at least partially answered. That it is going to cost more to build rolling-stock lighter than it is now for the same weight of load is evident. How much can a road afford to pay for making its rolling-stock lighter?

For a concrete example let us take the case of a motor-car of a very common type—viz., a closed motorcar with 16ft. body and double motor equipment, weighing complete 11,100lb. Its seating capacity is 22, and the weight of car per passenger seated is 504lb. This seems like an enormous dead-weight, but it must be remembered that the car must be prepared to carry at times as many people as can crowd on, and in some cities it will be called on to carry 60 or more people several times a day. This would bring the dead-weight down to 185lb. per passenger. On open cars with seats running clear across the dead-weight per passenger seated is considerably less than with closed cars.

Suppose now that it were possible by more expensive construction, and in some places the use of different materials, to cut the weight of our 16ft. closed motorcar one-half without weakening it. How much is the reduction in weight worth to the operating company? The first and most important saving will, of course, be in power, although a reduction in car weight would be far-reaching in its effects, having an influence on the cost of construction and maintenance of the track, overhead feeders, and power station—three of the most expensive parts of a street railway equipment. If the weight of a car and equipment is reduced 50 per cent. it will theoretically reduce the power required to run it 50 per cent. However, as the various losses, both electrical and mechanical, will be proportionately larger for the light car, we will assume that reducing the car's weight 50 per cent. will reduce the power needed 40 per cent., which is probably a conservative estimate. The average cost per car mile for power taken from the tabulated reports on power plant performance, published in our contemporary's issue, April, 1896, was ¾d., and the yearly cost of running a 16ft. car will be figured on that basis. If the car runs 3,000 miles per month its yearly mileage will be 36,000, and the cost of power taken to run it that distance at ¾d. per car mile will be £108. Forty per cent. saving of £108 would be £43. 4s. a year, or enough to pay interest at 6 per cent. on an investment of £720. According to this the average road could afford to pay £720 more apiece for its motorcars than it is paying now if they could be reduced 50 per cent. in weight without sacrificing any strength. There are some roads where power costs twice the average amount assumed, and they could consequently afford to pay twice the amount estimated for the sake of lighter cars. On the other hand, there are some that get power for half the assumed figure, and they consequently could afford to pay only £360 more per car. This takes account only of power saving. There would be other economies, as before mentioned. If car, truck, and motor builders see anything in these figures that make it any inducement to attempt any great reduction in weight, there will, of course, be a move in that direction. Cutting down weight without losing strength is, however, an expensive process, and it is useless to try to predict what can or what cannot be done along this line. One thing should not be forgotten, which is, that the parts of a car are dependent on each other, and the lightening of one part allows the

Digitized by Google

lightening of others. The lightening of a car body permits the lightening of the truck that carries it and the motors that propel it. The lightening of the motors in turn allows the trucks to be lightened, and so on.

METERS.

The following are the conclusions arrived at by Mr. James Milne in a paper read by him before the Canadian Electrical Association at Toronto. As the greatest part of the author's paper is devoted to the Edison meter, the gist of his conclusions can be understood. It is a pity, however, that he has not recognised any of the known defects in this type. He sums up the advantages and disadvantages of the various meters as follows:

The advantages of the Edison chemical meter are:

1. Practically no loss.
2. No moving parts.
3. Absolutely correct at all loads.
4. Will record the smallest possible amount of current.
5. It is applicable to any pressure.
6. Low first cost.
7. Low cost of maintenance.
8. Readily repaired.

The only disadvantage (if any) is that the consumer can't read it for himself.

Motor Meters.—The only advantage is that the consumer can read the meter. The disadvantages are:

1. Loss in overcoming friction in the moving parts.
2. Incorrect at light loads.
3. Incorrect at quickly varying loads.
4. First cost high.
5. Cost of maintenance high.
6. Not readily repaired.

Clock Meters.—In the Aron type of meter we have the following advantages:

1. Correct at all loads.
2. Will record the smallest possible current.
3. As a coulomb meter is applicable to any pressure.
4. Practically no loss.
5. Can be read by the customer.

The objections to this meter are:

1. Liability to stop recording if clock stops.
2. First cost high.

We therefore see as a practical meter the chemical meter is superior in every point save one, and that is, the customer can't read it for himself. Is this much of an objection? How many gas consumers read their meters? I know I am not very far out when I say that not over 2 per cent. ever wish to read their meters.

The Edison meter has been condemned by a certain class, either through ignorance of its principle or prejudice, and our Canadian Government has also seen fit to practically condemn it—probably not condemn it, but to curtail the growth of a meter that has no superior and very few equals.

It does seem strange to me that the Government should interfere the way it has done, and more especially with the electrolytic meter, when in the "Act representing the units of electrical measure" in Section B, lines 14 to 21, under the heading of "Ampere," it states "as a unit of current the ampere, which is ·1 C.G.S. unit, and is represented sufficiently well for practical purposes by the unvarying current, which when passed through a solution of nitrate of silver in water and in accordance with the specifications contained in Schedule 1 to this Act, deposits silver at the rate of ·001118 gramme per second." What does this mean? It means that they have practically adopted the chemical meter for determining the unit of current. In the Act it says the electro-chemical equivalent is ·001118 for a silver voltameter just the same as 00034 represents the grammes deposited per coulomb in a zinc or ·000305 for a copper voltameter. It is immaterial whether they specify silver, copper, or zinc, the principle is exactly the same, and it does look absurd on the face of it when the unit of current ·1 C.G.S. unit is according to law laid done as above, yet in the same Act a meter on precisely the same principle is limited to the extent of the number of meters in use at the time the law came into force. It may be argued that it is not the principle of the meter that is the objectionable point, but that it is not self-recording, the law, of course, calling for "dials." If any consumer wishes to keep a faithful record of the number of hours he burns his lamps he is at perfect liberty to do so, and if he does so conscientiously and the lamps are of the efficiency they are said to be, I suppose then the bill rendered from the meter reading will coincide exactly to a cent.

Again, it has been claimed by some holding important positions that to be renewing the zincs is practically renewing the meter—that is, supplying a new meter. Did you ever hear of such gross rot? What is the law on this point? It is "that the present number must not be increased, and all new meters must be of the direct-reading type," or words to that effect. The Government has to raise a revenue, that is settled; the gas companies contribute a certain percentage of that revenue, the electric companies are their greatest competitors; therefore we can readily infer that any little obstacle that can be put in the way by such companies will be done, and it is very common property that this Act was the result of the gas companies. May I ask, "Where did the Government get hold of that definition of the ampere, and also the voltameter specification? How are we to determine from this the alternating unit of current?" Has the Government inspector created any better feeling between the companies and the consumer? Do consumers pay their bills with any better grace than before the law came into force? Do customers put any faith in this test? Are there any advantages to be derived from this test? If so, where? The answer to the first three is in the negative, and the fourth in the affirmative, and to the last I will leave it unanswered for the present.

Probably I have digressed from the line of these papers, and in returning the same I wish to again draw your attention to the advantages as enumerated above in the electrolytic meter. Is there another meter in the market that can lay claim to the same?

[It is a pity that the author does not recognise the difference between alternate current and continuous current when drafting his conclusions, as from the body of the paper one would infer that even for alternating currents the Edison meter had advantages. We do not think that this class of contribution tends to advance the character of the institution before which they are read.—Ed. *E. E.*]

THE ELECTRIC LIGHTING OF CALCUTTA.*

The planning of electrical supply for a large city is a somewhat complicated matter. It differs essentially from the drafting of a gas or water scheme in that there exist numerous systems or methods more or less adapted to different-sized areas and varied peculiarities of local circumstance. It is apparent that the object to be attained by the engineer is a supply safe, reliable, and suitable to the public and private requirement at a minimum of current outlay.

The scheme proposed by Messrs. Kilburn and Co. does not in our estimation promise to secure to the city of Calcutta the above-named advantages. From that com pany's public notification dated June 10 we learn that they intend to light an area some 4,4 miles long and 1,6 miles broad "by means of the low-tension continuous-current system. The electricity to be generated at *one station* and stored in secondary batteries at sub-stations, and from thence distributed by means of distributing mains throughout the specified area of supply . . . or by means of such other system as shall be approved of by the Local Government, subject to the regulations and conditions for securing the safety of the public and for ensuring a proper and sufficient supply of energy as the Local Government may from time to time impose." The reference to some "other system" made herein must

* This is an editorial article from the current issue of *Indian Engineering.*

Digitized by Google

apply to improvements in electric lighting methods to be discovered in the future, so important as to warrant their adoption in place of Messrs. Kilburn and Co.'s proposed low-tension scheme; for it cannot be that a company, presuming to light a city of the importance of Calcutta, should evidence uncertainty as to which system they intend to adopt when applying to Government for an electric lighting license.

We have thus to discuss the merits of the above-mentioned system, which is apparently to Messrs. Kilburn and Co.'s thinking the best for the purpose. The voltage specified by them demands in the first place attention. As all systems now in general use provide low-tension distribution on service lines, no special merit attaches to the proposal on this account: other systems are equally harmless to the user. It remains to consider the advantage of low tension in the primary or distributing mains. Here it is true that its use guarantees immunity to the unauthorised and mischievous party who meddles with mains, which high tension does not. Beyond this we fail to discover any notable claim in favour of low-tension primary supply to be served from one station over an area of the considerable size here in question. For low-tension means by Board of Trade definition a tension not exceeding 300 volts, and it is well known that distributing tensions of 2,000, 5,000, 10,000, and even 20,000 volts have been successfully and practically employed to the present. We can point to the gigantic Tivoli-Rome, London, and Lauffen-Frankfurt works, among a host of others, in support of this statement.

Now it is apparent that if distribution takes place at a tension of 3,000 instead of 300 volts, the section, and consequently the cost of primary mains, will be enormously reduced, and with it the proportionate quota of repairs, interest, depreciation, and redemption. Apart from this it becomes economically possible by the use of high tension to reduce the total percentage of losses in the mains alone to from 10 to 15 per cent. of the total output; whereas low-tension distribution over an area of the extent in question could scarcely be achieved, commercially considered, with less than 35 to 40 per cent. of corresponding loss. Now, supposing even it could be shown that for this case the cost of low-tension supply would be equal, or nearly equal, to that of high-tension, we maintain that it would still be a mistake to sanction the use of low tension, for the area in question does not represent the whole of the present city of Calcutta. We have on the other side of the river a large station and an industrial district of the first importance which ought certainly not to be overlooked in the planning of any project for the supply of light and power. We have furthermore to keep in view the continual extension of our boundaries; and to establish supply works which can be simply and uniformly extended to meet the calls of every increased demand which the future may hold in store.

In the second place, we have to comment upon the proposed utilisation of electrical storage batteries. The claims put forward with respect to these are numerous. They are said to effect a reduction in the first cost of the generating machinery; as a smaller plant may be worked longer hours and with better economy while charging them. We find, however, that the advantage claimed in this respect is more than balanced, for areas such as the present, by the cost of the storage cells, their location in sub-stations, and the repairs and attendance they require. It has indeed been maintained by those interested in the sale of such apparatus that, for equal output, the total cost of wages and salaries, management, repairs, and maintenance, is less for storage battery than for alternate-current distribution. Statistics of some of the best British practice however, completely refute this assertion. We find by comparison of the records of six important battery stations with six such stations in which high-tension distribution is employed that the above charges average for the latter only 72 per cent. of those of the former description. Apart from this, we should deprecate any extensive employment of storage batteries in their present state of development in circumstances such as we have to deal with in Calcutta. It is sufficiently well known in technical circles that accumulators even in Europe require most skilled, careful, and constant attention to prevent their decay and failure. If that be the case there, it would be so to a considerably increased measure in this country, where the services of skilled hands have, moreover, to be dearly paid for. Though local experience as to storage is not very extensive, so far as it has been brought to our notice, it bears out our above remarks completely; one or two successful installations have to be set against a considerable number of failures.

That the Calcutta Municipality should incur such risk when other more promising, simple, and well-tried methods are at their disposal is not to be anticipated. The high-tension alternating systems have been frequently attacked on the head of the increased outlay for fuel which they demand as compared with storage distribution supply schemes. This objection is without question justified, and it will therefore be well to investigate its comparative importance. We find from statistical reference that per unit delivered we have to anticipate, with British circumstances, a difference of roughly 25 per cent. in coal consumption between alternating and storage supply. As the cost of coal, paid for at 16s. per ton, averages about 20 per cent. of the total maintenance costs of a supply station, these costs to include working expenses, management, depreciation, and redemption, it results that an increase of 25 per cent. on coal alone would result in only 5 per cent. increase in the total current expenditure, or even less at the lower price of coal in Calcutta. Had we not to set against this the higher efficiencies obtainable in the primary circuit and distribution apparatus of high-tension alternating plant, the merit of the extreme and superior simplicity of the latter, and the facility with which it is controlled should commend it to a first place in the estimation of Indian engineers.

That we do not stand alone in our above opinions concerning alternating-current supply is evidenced by the enormous footing it has gained of late years both in Great Britain and on the Continent. With respect to the United Kingdom only we are informed by Dr. J. A. Fleming, F.R.S., in his paper on alternate-current transformers, that "there are at present about 50 alternating-current electric supply stations in the United Kingdom, supplying not less than 1,100,000 8-c p. lamps," corresponding to an expenditure of 54,000 h.p. Apart from the immense value as a lighting agent, however, the alternate current affords the most remarkable facilities for the transmission and distribution of energy in the form of motive force, a matter of the utmost importance in an industrial centre. The difficulty of obtaining sufficient motive power at a low cost for the service of *small* industries is completely overcome by its means; and the electromotors, giving out 400 h.p. to 600 h.p., now in use in Kolomna, Riga, Tokio, and other places prove its practical utility also where very *considerable* forces are concerned. This latter consideration obtains weight also from the widely-discussed proposal of introducing electrical tramway service in place of the apparently unsatisfactory horse traction now in vogue.

In summary of the results of our foregoing discussion we find in favour of alternate-current distribution—including, of course, single and multiphase systems—as compared with the low-tension, single central battery sub-station system, that the alternating distribution is (1) effected with equal safety to the consumer; (2) with less loss in the mains; (3) at a greatly reduced cost of the latter; (4) that it possesses unparalled facilities for increase of output and the supply of larger areas from one central; (5) that the cost of up-keep and management, exclusive of fuel, is lower and the management more simple; (6) that it is more reliable, as the risk incurred by the use of batteries is abolished; (7) that it is most admirably adapted for the transmission and distribution of force.

Against this we have only to set, in favour of the low-tension battery scheme, a slight reduction in coal consumption per unit produced by the generators. With regard to the latter, we would distinctly state that from British statistics we find the total cost of supply per useful unit no higher for alternating stations than for such as make use of storage batteries.

Before concluding our remarks we have to dispose of one more claim in favour of storage battery supply—namely, that the latter is ready to meet demand when generators

Digitized by Google

are out of action. This claim might be enforced with reason had we to deal with a private installation of such small demand for night and day current that the generators could not be run continuously with desirable economy. But in every supply station of importance provision is most amply made, and reserves maintained to meet the current demand of every hour during both day and night, and the failure even of a generator unit in action would not as a rule interfere with the regular current supply for more than three to four minutes. In a former issue we have expressed some of our opinions with regard to the description of main conductors we think most adapted for use in Calcutta. Those remarks must be read in the light of our present article, as they are intimately connected with our advocacy of the high-tension alternating-current system on the basis of its superior merits.

The technical aspect of Messrs. Kilburn and Co.'s scheme is unfortunately not the only one from which we must withhold our approval. We think, however, it may safely be left to our local leaders in finance and the sages of the London market to sift the value of the project as a commercial enterprise, with due reference to the public notice of June 10 last and the stipulations contained in the license applied for to Government by the firm in question. No pains has evidently been spared over the concoction of this document, which comprises some 30 half foolscap pages of print; but, in spite of its ample volume, we feel assured that many of its stipulations and omissions would result, were it ever adopted, in disagreement, and loss both to the prospective user and to the speculating investor.

THE SUCCESSFUL HANDLING OF STREET RAILWAYS WITH THE DESPATCHER'S TELEPHONIC SYSTEM.*

BY J. L. M'LEAN, CHIEF DESPATCHER, LOS ANGELES.

Never has the history of the nineteenth century been marked with such wonderful improvements as those which have been introduced in the method of operating street railways throughout the United States during the past five years, principally by electricity and bringing the telephone into active service, electricity proving itself such a phenomenal success from every standpoint that now nearly four-fifths of the street railway mileage of the United States is operated by its use. While the telephone is also used very extensively, and each day adds to the number used by the street railways, yet to use it in connection with the operating department of a street railway system, such as the writer will hereinafter describe in full, will prove itself as big an improvement over the ordinary methods employed as the electric motor surpassed the horse-car. After changing from the "joggy, weather-beaten horse-car," the "greasy, jerky cable," or "blackened steam motor," to the electric motorcar, where an assured and reliable service could be depended upon, the difficulties of knowing how to obtain such requirements from an economical standpoint baffled the minds of managers and superintendents of the various street railway companies of our advanced country, which have undergone such changes and reorganisations, and even at the present day there is not a slower class of people in the country to pick up a good improvement, or even investigate its merits, than the managers of Eastern roads, who expend thousand upon thousands of dollars every year unnecessarily in the operation of their roads where the old-fashioned system of "time-cards" and "large numbers of stations" are used.

There is no reason why the service of an electric or cable railway improperly managed should not be looked upon as being even worse than the horse car, which occasionally does reach its destination on time, even though it may come two-thirds of the way with one set of wheels off the track, while there is every reason in the world why the service of such roads properly managed should surpass anything ever introduced.

A few things which are not only unpleasant to the public and very expensive to the company that are daily experienced in the operation of over half the electric and cable railways throughout the country at this advanced age (and for which we now have a thorough practical and cheap remedy) are the delays and interferences to the traffic, such as an electric car breaking a trolley, breaking an axle, burning out an armature, or becoming disabled in other ways which cannot be repaired while on the road, as well as accidents and jumping the track. Where the ordinary system of running cars on time-cards and by starters is used, the latter, being at the ends of the roads only, are unable to observe any trouble or interference to the traffic that may be going on until they find that the cars have stopped coming, and discover that they are all blocked at some point on the road. As is a natural result, where so much of the company's business interests and welfare are entrusted to the judgment of the trainmen, before it is possible for a person to catch a car going in either direction he is ordinarily compelled to wait the length of time that it requires to make a round trip on such line that is blockaded. Besides the amount of expense attached, as well as the decrease in the daily receipts where several such things have occurred in one day, the service may yet further be impaired and irregular on account of such disabled car standing at some far-out-of-the-way side track, or perhaps in the car shops, leisurely awaiting the orders of the shop foreman. And it is but natural with the remaining cars on the line, which have always been accustomed to running on a time-card and making just so many trips for a day's work, to continue running on such, regardless of the fact that there is a double and unprotected space in the service making its rounds, and that there should be some system, when a car goes into the shops from any cause, whereby the remaining cars could be uniformly spaced apart during the course of such blockade. Then in most places when a car is started from the shops to run in place of some disabled car, nine times out of ten the crew of such car will go to the wrong end of the line on purpose to have as much lay over time as possible before getting into their proper place. With cable cars they are invariably "breaking grips," dies, or shanks, losing a brake shoe, breaking grip lever, or becoming delayed from street obstructions, such as lumber, coal, or stone wagons breaking down across the track, which all consume from five minutes to three-quarters of an hour delay or lost time in the service. Seldom is there a delay of any description on a city railroad but what a double space in the service is caused, and on a cable railway where there is the ordinary service a cable car cannot make up delayed time, but is liable to lose more time owing to the space there is ahead of it, and the time of day, unless it be on a down grade, when the grip can be released and run faster than the cable, only to endanger the lives of passengers as well as the gripman himself. Hence, we have the same results here as from the derailment of an electric car, which is, that a double space in the service is making its rounds, and most generally at a time of day when the traffic is the heaviest and when the service should be at its best. The system and improved method of despatching cars by telephone is composed of an entire private telephone system, the central office of this system being known as the despatcher's office.

Telephones are stationed at the terminus of each line at which conductors on arriving each trip report their car number to the despatcher, and from him obtain their leaving time. In most places the instruments are placed in small canopy-top houses, built especially for this, and are thus protected from all sorts of weather; though they are sometimes placed on poles, in boxes, with lock and key, each conductor being provided with a key. On trunk lines that traverse one end of a city to another, telephones are placed at certain intervals and important points—such as drawbridges and steam road crossings—and are known as emergency 'phones, to report delays, breakdowns, trouble with overhead line or track, or anything that the despatcher should know to successfully operate and maintain an efficient service. The wires leading from all of these 'phones run directly to the despatchers' office, where they are connected on to a neat glass-front switchboard, about 20in. by 12in. by 8in. in size, stationed on top of a neat oak desk, which is about 9ft. long, at which two despatchers can work at the same time when

* From the *Street Railway Review.*

Digitized by Google

necessary, and is known as a combination desk and switchboard. The transmitter, adjustable by means of weights and pulleys, also hangs directly in front of him. A system of magnetic and gravity drops works in connection with a signalling system of small incandescent lamps, the latter being placed back of a stencilled number representing each circuit, which when lighted indicates the circuit calling. A set of cam lever switches which the despatcher works with his left hand restores the drop to its normal position, which, when pulled down, also put out the corresponding lamps, and puts him in direct connection with the party calling. He is provided with a large sheet, 21in. by 24in., on which are listed the numbers of all cars in their regular order, under the proper headings of each line. He is thus enabled to despatch two to seven cars per minute, recording the time each one should leave the terminus on his sheet. A glance at this sheet gives him the immediate condition of the entire system and exact location and direction of each car.

Of course, the calls do not come in uniformly, but vary a great deal owing to the number of cars in operation. The space between cars also varies, as does the number of cars in operation, which is governed by the traffic at different hours of the day in most places. The despatcher's duties have been largely increased owing to the many calls that come through the switchboard from the public telephone exchange to the circuit. But by means of a system of push buttons, running to each officer in the building, he is without the slightest exertion enabled to summon any officer to the public 'phone, which is stationed handy to everybody. He also receives reports from the trainmen, of which he makes a daily report to the general superintendent as to the condition of the cars; such as brakes, trolley, motors, brushes, or lights, or anything being out of order that would likely prevent them from making their schedule time. To keep the car from going in the shops, if possible, this is also immediately reported to the proper departments by the despatcher. He also gets a full report from the conductors of all delays which have happened in connection with their cars during the day of two minutes or over, which, at the close of his shift, are forwarded to the general superintendent's office, together with a report of all cars that have been run in the shops, showing name of motorman, cause, time of day, and number of the replaced car.

As I have before stated, the despatcher is in close touch, by means of telephone, with all of the car houses, shops, division and general officers, including the general superintendent, claim agent, surgeon, foreman of overhead line and wrecking departments, in case of any interferences to the traffic or accidents, so that on a moment's notice any member of these departments may be summoned.

In case of blockades at any point, the despatcher, by being able to communicate with both ends of any line, can maintain a certain service during the course of such blockade, as well as prevent the cars from all bunching at any point by lengthening the space between them, sending them out on a larger headway, and, if necessary, he can on a moment's notice order out extra cars or "trippers," as they are called by some, depending altogether on how long the blockade will last and the demands of the traffic at such time.

The watches of all the trainmen are compared from one to three times a day and kept regulated with the large clock in the despatcher's office, which is the standard time of the system, and which governs the movement of all cars. This time is always obtainable at any point where an instrument is stationed for reporting.

The despatcher is held responsible for the movement of each car. All report to him on each trip between 6 a.m. and 12 or midnight from the ends of their respective lines. No time-card whatever is used where this system is employed. The cars are started in the morning from the various houses at a certain time, and are allowed so much time in which to run from the house to the end of the line, where they report to the despatcher, and from him obtain their leaving time from such point. Different schedules of running time between points are employed at different hours of the day, owing to the demands of the traffic. These schedules are regulated by the despatcher. "Extra cars" and "trippers," before leaving the car-houses at different hours of the day, in all cases report to the despatcher, giving him their car number and the line upon which they are to run. In reply he gives them the leaving time and direction to go, as it often occurs that he can despatch them to fill in a double space that may be coming or going in either direction on a line. The moment that a report is received giving notice of a blockade, the despatcher ascertains the number of the car, and a glance at his sheet gives him the direction going; whereupon he immediately begins to lengthen the space between the cars ahead of the delayed one as fast as they report, taking into consideration the nature of the delay and about how long it will continue. In the meantime he may have summoned either the wrecking car or wagon. Then the moment he receives the word that the blockade is raised, another glance at his sheet and the large clock in front of him gives him the exact location of each car, when, as fast as they report, he begins to despatch them from the ends on their regular space.

I claim for the despatcher's system flexibility and quickness in the adjustment of all cars; also that one ordinarily bright man to act in the capacity of a despatcher can do more from the standpoint of the company's interest towards maintaining a service during the course of blockades and interferences with the cars on a half-dozen lines in 15 minutes, than 15 starters and men on the street can do in an hour. For illustration, take a line with 30 cars on, running on a three-minute headway, allowing 90 minutes for the round trip. We will say car No. 1, according to running time, is due to leave terminus "A" at six o'clock; car 2 in order at 6.3; car 3 in its order at 6.6; car 4 in its order at 6.9, but does not arrive until 6.13, being four minutes late, and having in front of it a seven-minute space at a time of day when it is impossible to make up time. Car 5 arrives on time, at 6.13, but is held until 6.17, hence all cars following have a lay over of four minutes at terminus "A," save those which were held an additional minute at terminus "B" to offset the delay at terminus "A" in running time, and thus have the seven-minute space of No. 4 protected by the time he reaches terminus "B." Whereas, under the ordinary system of "time-card" this car would carry the seven-minute space a round trip over the line before catching up to the other cars on a three-minute space.

I therefore claim that street railways can be more successfully handled with "the despatcher's telephone system" than any other method.

The despatcher's system was put into active operation in 1890 on the Denver tramway, operating 100 miles of electric railway. The writer later on successfully installed the system on the City and Suburban Railway of Portland, Ore., operating 55 miles of electric railway, and in a recent letter received from the manager of that company he stated that the system was not only giving them perfect satisfaction, but that they would not attempt to operate their roads again without it.

The writer has just completed the installation of the system on the lines of the Los Angeles Railway, operating 104 miles of electric railway, comprising 11 different lines in the city of Los Angeles, Cal., which is considered one of the finest systems of electric railways on the Pacific Coast.

THE ROASTING OF IRON ORES, WITH THE VIEW TO THEIR MAGNETIC CONCENTRATION.*

BY PROF. H. WEDDING, BESSEMER GOLD MEDALLIST.

Long before iron ores were smelted for pig iron in the blast furnace roasting processes were employed prior to the direct extraction of the metal from the ore, and after the introduction of the blast-furnace process the roasting of iron ores was still retained. As a rule, the roasting is a preliminary to the reduction process. It is only exceptionally or incidentally that it has to effect the purpose of simultaneously eliminating elements, such as sulphur or arsenic, that could detrimentally influence the iron produced. It is only in very recent times that roasting processes have also been employed in order to render iron ores magnetic, so that they can subsequently, by magnetic concen-

* Paper read at the meeting of the Iron and Steel Institute at Bilbao.

Digitized by Google

tration, be freed from gangue—that is, from constituents not containing iron, and be enriched in iron.

On considering the composition of the ferruginous constituents of the ores practically employed in the metallurgy of iron, there will be found, as a rule, in the ores supplied by nature, oxides, hydrates, and carbonates of iron: magnetic oxide in magnetite ores; ferric oxide in red hæmatite ores; ferric hydrate in brown hæmatite ores; ferrous carbonate in spathic iron ores, clay iron ores, and carboniferous iron ores. If sulphur compounds occur, which have to be used as iron ores, as, for example, iron bisulphide in iron pyrites, they must always be first converted into ferric oxide (purple ore) before the material can be further utilised in ironworks practice. Again, from the hydrates water must be expelled, and from the carbonates carbon dioxide, before the iron of these ores can be reduced.

The heats of combination of all iron ores show that a reduction to iron cannot occur as long as sulphur, water, and carbon dioxide are still present. It might consequently be assumed that the only object of roasting was the expulsion of sulphur, water, and carbon dioxide, with a view to the reduction of the iron, were it not that the practical facts were in contradiction to this, in that they show that as a matter of fact even more iron ores that contain neither sulphur, water, nor carbon dioxide, but that consist only of magnetic oxide or ferric oxide, can with advantage be subjected to roasting. The object of this is either to facilitate the subsequent reduction by the formation of the most easily reducible oxygen compounds, or to facilitate the reduction by loosening the texture of the iron ores

[Before taking up the question of magnetic roasting, the author considers the question of roasting as a preliminary to reduction. We have, however, omitted this section, as it is not so interesting to our readers.—Ed. *E. E.*]

Roasting Iron Ores for Subsequent Magnetic Treatment.

The farther is the utilisation of the world's store of iron ores carried, the rarer become those ore deposits which, combined with adequate richness, are sufficiently pure for blast-furnace treatment and still much rarer are those which appear adapted for the open-hearth process—that is to say, for the manufacture of ingot iron from pig iron in the reverberatory. The question of the concentration of iron ores is becoming year by year more and more pressing for iron metallurgists. The prosperity of a country is dependent on its iron industry, but largely, too, on the iron ores it uses being mined in the country itself. Rich and pure iron ores still exist, it is true, in adequate quantity, but they are confined to a few places in different countries. Our excursion brings us to Spain, the country which provides all the iron-producing countries of Europe with ores of this kind. Sweden is not less rich in ores such as these, but how long will these sources of supply be available? The iron metallurgist finds it day by day a more pressing matter to enrich and improve unsuitable iron ores, and for this purpose magnetic concentration occupies the foremost place. Of the different compounds of iron with oxygen, practically only the two oxides Fe_6O_8 and Fe_6O_7 are adequately magnetic. Ferric oxide is nearly non-magnetic, and ferrous oxide cannot be produced in practice. On the other hand, the ferric oxide in red hæmitite, or in dried brown iron ore, may be readily rendered magnetic by roasting—that is to say, may be readily converted into the magnetic oxide. Three possibilities exist in this direction. When the atmosphere during roasting is oxidising in character—that is to say, when air is admitted—either the ferric oxide is converted into the magnetic sub-oxide Fe_6O_7 or Fe_6O_8, or else by the accurate roasting of carbonates a magnetic oxide is produced, or from the oxide, Fe_6O_9, by a reducing roasting a magnetic lower oxide is obtained.

Whether any one of these methods will be profitable is mainly a question of cost. The reduction is certainly rendered more difficult, the fuel consumption during reduction becoming greater, and the magnetic roasting with the subsequent treatment also in itself entails additional expense. Probably, therefore, in most cases a preliminary preparation of the ores for the blast-furnace treatment will be out of the question. On the other hand, a pure ore, despite great cost, may in many cases prove useful in the open-hearth process—that is to say, in the oxidising fining for ingot iron in a reverberatory provided with heat-regenerating chambers, by means of which, that is, molten pig iron is converted into molten malleable iron. One sees, therefore, that the question as to what is to be done to convert non-magnetic ores into magnetic ores is by no means one that should be overlooked, but that it is rather of great importance.

Phillips has published an account relating to the magnetisation of the red iron ores of Birmingham, Alabama, with a view to the necessary further concentration by the magnetic process. If the observations of this writer are taken into consideration jointly with the results obtained at Allevard, in France, which I have described, one obtains from these perhaps the only cases in practice in which iron ores that are non-magnetic by nature are prepared by roasting for a subsequent magnetic treatment. The first case relates to the roasting of ferric oxide, Fe_6O_9, and the second to the roasting of the carbonate, $FeCO_3$, for conversion into the magnetic oxide.

Magnetisation of the Various Iron Ores.

1. *Magnetites.*—Magnetites are of themselves magnetic, and do not therefore need to be first rendered magnetic before they can be submitted to a magnetic concentration. Nevertheless, roasting may be necessary for such an ore, partly for the purposes of facilitating its further reduction in size for the magnetic treatment by rendering it more easy to break down, and partly for the purpose of eliminating the sulphides it may contain, such as iron or copper pyrites or zinc blende. Magnetites only lose very slowly their natural magnetic properties on roasting, no matter whether the roasting is oxidising or reducing in character. Only when they are maintained for a very long time at a medium red heat and with access of air will the magnetic oxide pass gradually into ferric oxide and the ores cease to be magnetic. On this point Phillips has made detailed investigation. He made a large series of experiments and heated portions of native magnetite in a strongly-oxidising flame for 30 minutes without influencing their magnetic character. At a dull red heat in an oxidising flame some pieces lost their magnetic power, but regained it when raised to higher temperatures. This regaining of the magnetic properties is a fact which was noted long ago by H. Rose, who showed that on heating an iron oxide in a porcelain furnace, the oxide partly lost its oxygen and became magnetic. In a similar manner native magnetite can absorb oxygen and lose its magnetic properties, but regain these when heated to a still higher temperature—the first time through absorption, and the second through loss of oxygen. In this connection it may be pointed out that the artificially-prepared magnetite does not behave so favourably as the native mineral, but loses and regains its magnetic character more readily.

2. *Spathic Iron Ores.*—From the carbonates, by suitable roasting, the magnetic iron oxide can be obtained direct. By roasting in a neutral atmophere the "ignition" magnetic oxide Fe_6O_7 is obtained, and by roasting in a moderately oxidising atmosphere, the magnetic oxide Fe_6O_8. If, however, the carbon dioxide is once eliminated, both these magnetic oxides pass readily under the action of the oxygen of the air into the non-magnetic ferric oxide Fe_6O_9. If, therefore, it is desired to produce the magnetic oxide, the whole success depends on roasting with exclusion of air, or, if this is impossible, on reducing the air access to a minimum. The ferric oxide which is produced when there is free access of air is, however, at higher temperatures, just as decomposable again into the magnetic oxide and oxygen, as has already been referred to in connection with the native magnetites. It is possible, therefore, without endangering the magnetic character of the product, to roast spathic carbonates at temperatures as high as may be necessary to eliminate as far as possible the sulphur occurring in the spathic ores as iron and copper pyrites, zinc blende, etc. On the other hand, this necessitates a larger consumption of fuel than would be necessary if the spathic ores were only to be converted at a low temperature into the condition of the magnetic oxide. For the preparation of magnetic oxide from the spathic carbonate, no reducing roasting atmosphere is consequently necessary.

3. *Red Hæmatites.* — Magnetic oxide can be prepared from the ferric oxide of red hæmatites in two different ways: (1) By heating strongly in the absence of air. One atom of oxygen separates off in this way, and, indeed, by properly firing two oxygen atoms may be eliminated—$Fe_6O_9 = Fe_6O_8 + O = Fe_6O_7 + 2O$. For this reduction of ferric oxide, as Phillips has shown, a relatively very high temperature is necessary, at which, if the red hæmatite contains a quarzose gangue, slag may readily form. In any case it is difficult, at the high temperatures at which this separation of oxygen takes place, to avoid a sintering, or even it may be fusion of the gangue with the ferric oxide, and the formation of an iron silicate. (2) The second method of preparing magnetic oxide from red hæmatites depends on the roasting of the ore under the action of reducing gases, of which at low temperatures hydrogen and at higher temperatures carbon monoxide are most suitable in their action. To be certain, therefore, it is best to employ in the roasting a mixture of both these gases—that is to say, to roast with ordinary water gas. The readiness with which the reduction takes place depends in both cases, with red hæmatites, largely on their more or less dense texture. Many red hæmatites are so excessively dense that just as little reduction takes place with as without the use of reducing gases, even when the ignition is long continued. On the other hand, blast-furnace practice shows that there is no red hæmatite which, given adequate time, is able to resist the reducing action of carbon monoxide, even completely down to the metallic state, and this reduction must of necessity be preceded by a transition through the different stages of the magnetic oxides of both kinds.

4. *Brown Iron Ores.*—Before the ferric oxide of the hydrated iron oxides can be reduced the water must first be eliminated. The residue then behaves as a red hæmatite would, but the reduction proceeds far more readily under the influence of reducing gases, owing to the more porous character of the ore

Digitized by Google

after the elimination of the water. Laboratory experiments have shown me that even from the iron oxides of the dehydrated brown iron ores, magnetic oxide may be prepared both by strongly heating with exclusion of air and by heating gently in reducing gases. Here, too, it is a question dependent on the character of the gangue contained in the ore as to which method is best to be employed. If one has to deal with ores containing no quarzose gangue, high temperatures may be used; if the ores contain intermingled sulphides, this must be employed, or in the first place the treatment must be oxidising, and then reducing in character. On the whole, for brown iron ores the method in which use is made of reducing gases at a low temperatures is most advantageous on economic grounds, owing to the saving of fuel.

5. *Pyritic Ores.*—Pyritic ores, before a reduction can take place, must first always be robbed of their sulphur contents, or at least mainly so. As in any case pyrites is subjected to an oxidising roasting for the purpose of obtaining sulphur dioxide from its sulphur contents, the residue is in practice always ferric oxide, and this ferric oxide behaves exactly as that of red hæmatite, except that it is a little more difficult to reduce, owing, perhaps, to the presence of some residual sulphur. As is well known, iron pyrites is only then used as an iron ore when it contains copper, or perhaps, too, zinc. In addition to the chlorides of the metals resulting from the oxidising roasting of the pyrites in admixture with salt, ferric oxide also results. The former are extracted by leaching with water, and the ferric oxide remains behind in a practically pure state. Purple ore is pure enough for magnetic separation to be unnecessary.

Size of the Ores to be Roasted to Magnetic Oxide.

The size of the ore pieces to be roasted to magnetic oxide is not unimportant. Before all things it is necessary, in order to obtain a good result, to have the pieces that are to be roasted as nearly as possible of the same size. It may be taken as a rule that the magnetisation takes place the more readily the more the ore is in the form of small but solid pieces which do not crumble up or fly into bits on roasting, since the gas can then readily pass through the interspaces, and the relatively small ore particles are rapidly converted into magnetie oxide right through their mass. A much larger size of the ore particles is disadvantageous, as for their conversion into the magnetic oxide too long a time is necessary, and since it is then uncertain whether this magnetisation has gone right through to the centres of these ore lumps. Phillips has very rightly pointed out, in opposition to the observations of Barton, that the magnetisation always takes place from the outside inwards, and never from the inside outwards.

Pulverulent or very small ore particles are excessively difficult to magnetise, since the passage of the gases through the small interstices is rendered very difficult, and the gases usually form small ways or channels, from which the conversion then begins. It is therefore very difficult to magnetise ores for magnetic preparation which have already been broken down very small, or are pulverulent—slimes, that is. All such experiments which have been made, as, for instance, those at Allevard, have led to results which have not been altogether satisfactory, as the size of the pieces to be magnetised was much too small. More important than the actual size of the pieces is the necessity for having them under all circumstances of a similar size, and one cannot therefore pay too great attention to ensure, by twice passing through screens before the magnetising roasting takes place, that all the ore pieces to be roasted have been brought to one and the same size.

Furnaces.

The requirements for the roasting of different kinds of ores, and especially of different ore-sizes, necessitate naturally the construction of different kinds of furnaces. Lump ores are always best roasted in shaft furnaces, in which an easy and regular passage of the ore through furnaces of circular section is obtained. The section of the furnace should widen slightly from the throat downwards in view of the gradual heating of the ores and their expansion. Inversely this leads also to a more regular upward passage of the furnace gases through the ore. It is therefore a question of causing the ore to pass through two different stages, first heating them, and then reducing them if they are oxidised, provided, of course, that they are red or brown hæmatites. This must be effected by using gas in two ways, partly as fuel and partly as the reducing agent. As Phillips has observed in his description of the roasting of red hæmatites, the gas for heating purposes is best introduced into a combustion-chamber in which it is burnt around the furnace, so that only the flame enters the furnace. It need hardly be mentioned that gases cannot be burnt without the presence of a not inconsiderable excess of air, and attention has therefore to be given to seeing that in the heating of the ore an oxidation is as far as may be avoided. Only in the case of red hæmatites which are to be reduced by the splitting-off of oxygen at a high temperature is a temperature to be employed which may be as high as is possible of attainment, and in this case it may be a matter of indifference whether an excess of oxygen is present or whether this is absent. In the case of spathic ores the only thing that is necessary is heating in the absence of air, with no subsequent oxidation, although here, too, the treatment with reducing gases can only be advantageous in character. The reducing gas, whether ordinary producer or (and better) water gas, must then be passed into the heated ore from a lower level, and caution is necessary to ensure that no air can enter. The openings which are to be employed for the withdrawal of the roasted ores from the furnaces must therefore be capable of being closed perfectly airtight during the roasting, and the brickwork, too, must be built so as to withstand the passage of air through it. To be able, however, to readily withdraw the ore, the reducing gas must be passed into the furnace at a level somewhat above that of the withdrawal doors. One obtains in this way the advantage that the gas in its upward passage at the same time cools down the hot ore, with the result that this arrives at the withdrawal openings in an almost cold condition. The space between the entry of the hot burnt gases and those used for the reduction ought never to be small, as is often the case in Swedish calciners. One of the principal conditions for properly roasting iron ores into the magnetic state is the keeping of a right temperature in every part of the furnace. Since the Le Chatelier pyrometer is made in the form described by the author (*Stahl und Eisen*, 1896, September), all difficulty in controlling the temperature is obviated, and the instrument may unhesitatingly be relied upon for this purpose.

In the case of pulverulent or fine ores, the use of shaft furnaces is not advisable, and it is better in such a case to employ zig-zag furnaces, such as were used at Allevard, or channel furnaces with inclined beds. Still, care should as far as possible be taken never to have to deal with such fine ore, but rather with ore of a coarser character.

Concentration of the Magnetised Ore.

The magnetised ores, after the roasting, must be submitted to concentration, which may in the first instance be mechanical in character, to separate from each other the ore particles of different sizes, and then magnetic, or it may be magnetic from the very commencement. This must be entirely dependent on the character of the ore as regards admixture of gangue and iron oxides. The finer is the state into which the ore is brought for magnetic separation, the more satisfactory will the progress of that separation naturally be, and the better will be the yield. The fine state of the ore has, however, in spite of this, various drawbacks. In the first place, as has been mentioned above, the magnetisation is, as a rule, by no means regular, and in the second, such finely divided ores can only be added with advantage in quite small quantities to the blast-furnace charge, former experience in this direction placing this maximum at 12 per cent. All methods, too, of converting this fine ore again into larger lumps are too expensive to be, at least, generally, commercially satisfactory. If, therefore, the ore is to be used in blast-furnace practice such very small ore must, as far as possible, be avoided, and the size should be kept at about that of hens' eggs. On the other hand, small and even pulverulent ore may very well be utilised in the open hearth, and it has for this field of operations, I think, a very wide scope indeed, for the scrap which is now necessary for the conversion of the pig iron into ingot metal in the open-hearth process is becoming year by year more difficult to obtain and more expensive to purchase, and it might very readily be entirely replaced by oxides. If the ores powder up readily on charging into the bath of pig iron, they may be enclosed in cases of sheet iron or paper (cartridges).

Very few ores are of themselves pure enough for the open-hearth process, and they cannot either be converted into an adequately pure form by mechanical concentration, so that there is scarcely any other way of purifying them which could prove itself commercially economical except the method of magnetic concentration, which, if the ores are not magnetic, must be preceded by a magnetic roasting.

PROPOSED SCHEME FOR ELECTRIC LIGHTING OF ABERDEEN HARBOUR.

We are indebted to the *Aberdeen Journal* for the following abstract of the report on the above subject, which is about to be presented to the Corporation:

Mr. Blackman, borough electrical engineer, and Mr. R. Gordon Nicol, C.E., harbour engineer, have, as instructed, prepared the report on the most suitable system of electric mains, lamps, and fittings for lighting the quays, and for the supply of electric power at Aberdeen Harbour. The quays, which it is proposed should now be lighted by electricity—viz., Waterloo, Regent, Trinity, Market, Provost Jamieson's, and Provost Blaikie's Quays—have an aggregate length of 2,400 yards, and vary in width from 20 to 48 yards. They are lighted at present by gas lamps of about 25 nominal candle-power,

Digitized by Google

spaced about 48 yards apart in two rows, one row on the edge of the foot pavement, being provided and lighted by the Town Council, while the other row is placed on the street, about six yards from the edge of the quays, and is provided and lighted by the Harbour Commissioners. At important places on the pavement and quays Bray's lamps of about 80 c.p. have been erected.

It is proposed that one row of electric lamps should be erected about the middle of the quays, of such a power, height, and distance apart as to provide sufficient light over the whole area of the quays, provision being at the same time made for the supply of portable arc or incandescent lamps to shipping at the quays when such lamps are desired. To secure this they are of opinion that arc lamps to carry 10 amperes of current and give about 2,000 nominal candle-power should be provided—elevated on standards to a height of 25ft. above the level of the street, and placed at distances of about 40 yards apart, lengthwise of the quays. They would be coupled up in groups of four lamps in a series, across the outside wires from the electricity works; the groups being combined in pairs in such a way that the switching out of one group would extinguish each alternate lamp over a length of 320 yards of quay.

The mains for the supply of electricity to the lamps would extend in a complete circuit round the docks, passing underneath the entrances to Victoria Dock, and have a feeder crossing the dock to a point in the mains at the south end of Regent Bridge. From the foot of Commerce-street along Regent Quay and Trinity Quay, where private consumers may be expected, the mains would consist of bare copper strip, laid in a concrete culvert in the foot pavement, with lead-covered cables in iron casings at the street crossings—branch conductors of armoured cable being taken across the quays, underground, to each group of lamps. From the corner of Guild-street, along Market Quay, Provost Jamieson's Quay, Provost Blaikie's Quay, under the dock entrances, and along Waterloo Quay to the foot of Commerce-street, they would consist of armoured cable buried directly in a trench in the ground in the line of the lamps.

The connections for the portable lamps to be hired out to shipping would require to be fitted up at the edge of the quays, as the traffic on the line of rails next the coping would otherwise be subject to interruption. In consideration of this they are of opinion that the cast-iron bollards on the edge of the quays could be made to contain the switches, connecting gear, and current meters, and would be most suitable for that purpose, the lamp wires being connected to the face of each bollard, and laid on board where required. The branch conductors from the mains would be passed underground and up into the bollard heads, the switches being operated and the meters read through a door in the side of the bollard. As they will require to be specially designed for this purpose, it would be advisable at present to provide such bollards on the new wall at Regent Quay only, or wherever new bollards are required, as they could then be made suitable at little additional cost.

The beacon lights for shipping traffic at tide times would be arc lamps carrying 30 amperes of current and giving about 6,000 nominal candle-power. They would be placed at the dock entrance and at Regent Bridge on lattice pillars, 80ft. high, and supplied with electricity from the lighting mains.

To provide a supply of electricity for motive purposes they are of opinion that the current should not be taken from the same mains as supply the arc lamps, as the intermittent demands upon the current by motors if worked at night would be certain to lead to fluctuations in the light. The power circuit would therefore be entirely separate from the lighting circuit and would consist wholly of armoured cable buried in the same trench as the lighting mains, where these are of armoured cable. It would commence at the foot of Commerce-street, and pass round the quays to the point of starting. From the power mains branch conductors would be taken underground to convenient points, where connections could be made by flexible wires to electric cranes and whips, and to the machinery of the new swing bridge, if this type of motive power should be decided upon to operate the bridge. The quantity of current used by each group of lamps would be measured by a meter placed on the base of one of the lamp-posts; there would also be a meter in each bollard head, while the current used by motors would be measured by a meter at each motor. The foregoing report is based on the assumption that the necessary electricity would be generated at the Corporation electricity works, the whole of the mains and branch conductors laid and maintained by the Town Council, and the lamps and motors erected and maintained by the Harbour Commissioners.

They estimate the cost of the works described above as follows: By the Town Council—mains and branch conductors for lighting circuit, including culverts and trenching, £5,000; ditto for power circuit, £1,750—£6,750. By the Harbour Commissioners—sixty 10-ampere lamps on quays, with posts, complete, £1,620; eight 10-ampere lamps in sheds, £96; six portable ditto, for shipping, with conductors, £120; three 30-ampere beacon lights, with pillars, complete, £750—£2,586. Total cost, £9,336.

A NEW TYPE OF CABLE ARMOURING.

We have received particulars of a new departure in the armouring of electric light cables introduced by Messrs. W. T. Glover and Co. The illustration below will explain the general design of this new cable, which is practically one with a bare return. The armouring is used as the return circuit, and consists of two parts, the iron or steel segments forming the mechanical protection and the copper wires the conductors.

It will be observed that the cables are completely sheathed with the iron or steel segments forming the lock armour, and the round wires of copper practically act as the keys locking the segments together. The surface of the lock armour is smooth and continuous and enables the cable to be nicely finished. It at the same time protects the cable from being pierced by picks or other sharp instruments which are liable to force their way through a round wire armour. The advantages of the copper wires in the armour are manifest.

If ordinary iron or steel wire armour is used for the purpose of conveying energy, and particularly in cables of large size, the weight of such metal required to accommodate the current is so great that the cables are both costly and unwieldy. Still, there is no reason why the iron armouring should not act partly as the return, and thus save a portion of the weight of copper required. The combination of the two metals in this armour is therefore a happy one, as the makers gain in three directions—*i.e.*, mechanical strength, conductivity, and cost of copper. Cables are often required having an earthed or bare return for use in coal mines and for shiplighting, etc., but we should imagine that to prevent electrolytic action between the two metals in the armour the outer serving of insulation will be adhered to.

We understand that Messrs. W. T. Glover and Co. will manufacture this type from the smallest to the largest size required for lighting purposes, the quality being guaranteed, and that the length in which such cables can be supplied is practically unlimited. Samples of this new cable—to give it its full name, Glover's patent high-conductivity lock armour—can be seen at the firm's London office, 39, Victoria-street, and at Salford, Manchester.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Spa (Belgium)—The Burgomaster and Echevins of Spa invite propositions for undertaking the public lighting, either electrically or by acetylene. The date fixed is September 15. No further information is given in the official advertisement.

Hamburg.—Tenders will be received on September 19 for an incandescent and arc lighting installation for the stages at Brookthurhafen. Application should be made to the Finanz Deputation, and a local guarantee will be required.

Berlin.—The construction of an iron bridge at Gitschiner-und-Skalitzer-street in connection with the electric tramway is open for tender. Application is to the Königl. Regierungs und Baurathes Bureau, Markgrafenstrasse 94, Berlin, and the date is September 28.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Odessa.—The Municipal Authorities have decided to offer for tender the electric lighting of part of the suburbs and the new prison. No date is given, and application must be made to the Municipal Delegation at Odessa, but certain particulars can be obtained at the Ministry of Commerce (bureau de renseignments commerciaux), Paris, rue de Varenne 80.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Digitized by Google

Amsterdam.—Up to September 12 the Consul-General of the South African Republic (Transvaal) will receive tenders for the supply of insulators with supports. The address is at Doelenstraat 8, Amsterdam. Specifications will be procured on demand by Mr. F. J. Belinfante, late A. D. Schinkel, Paveljoensgracht, The Hague, at the price of 1sh.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Voghera (Italy).—In view of the expiration of their contract with the local gas company in 1898, the municipal authorities of Voghera are desirous of receiving during the present year propositions for the lighting of the town either by the electric light or a mixed system of gas and electricity. The population is 16,000. Application should be made to L'Administrazione Comunale, Voghera, who will give all particulars necessary.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Oldham.—The Electric Light Committee invite tenders for the various works required in the extension and alterations of the buildings of the electric light station in Gas-street, Oldham. Specifications and drawings can be seen, and schedules of quantities obtained, on application to Mr. Arthur Andrew, Gas and Water Offices, Oldham. A charge of £1. 1s. will be made for the schedule of quantities, which will be returned on receipt of a bona fide tender. Tenders to be sent in by September 15.

Brussels.—Tenders will shortly be wanted (the date is not yet fixed) for installing the electric light at the Arlon Railway Station, including the offices and works. Particulars will be obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Edinburgh.—The Lord Provost, Magistrates, and Council are prepared to receive tenders for the wiring of the Burgh Assessments Office, High-street. Specification, forms of tender, and plans of the building can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, on deposit of two guineas, which deposit will be returned on receipt of a bona fide tenders. Tenders must be sent to the town clerk, Mr. Thomas Hunter, City Chambers, Edinburgh, not later than Tuesday, September 22.

Hull.—Pending the decision of the Town Council as to the leasing of the tramways or the working of them by the Corporation, tenders are invited for a license to temporarily work and use the tramways for one year from October 15, 1896, upon the terms and conditions embodied in the draft of an agreement, which can be obtained by application to Mr. R. Hill Dawe, town clerk, Town Hall, Hull. Tenders, stating the amount of rent offered, must be delivered at the Town Clerk's Office, by 10 a.m. on September 21, in sealed envelopes, endorsed "Tender for Temporary Working of Tramways."

Cadiz.—The Secretary of State for Foreign Affairs has received dispatches from her Majesty's Consul at Cadiz, stating that preliminary tenders for a supply of electric lighting apparatus for the illumination, on the most approved modern plan, of private houses, etc., in the town of Cadiz are invited by the "Sociedad Co-operativa Gaditana de Fabricacion de Gas." It appears that the tenders should be sent in by September 15 to the above-named company, whose offices are San José, 25, 27, and 29, Cadiz. Firms wishing to obtain the contract for the supply of plant are advised by the Consul to send representatives to treat personally with the company. Such additional particulars as have reached her Majesty's Government on the subject may be viewed at the Commercial Department of the Foreign Office, any day between the hours of 11 a.m. and 6 p.m.

Morley.—The Electric Lighting Committee of the borough of Morley are prepared to receive tenders for the supply and erection of the following plant. (The whole bound up in one specification; price £2. 2s., returnable on receipt of a bona fide tender): Section A—Boiler-house plant: Lancashire boilers and fittings, feed pump, etc. Section B—Engine-house plant: steam alternators and exciters, motor alternator, accumulators, steam and exhaust pipes, valves, etc Section C—switchboard and instruments. Section D—overhead crane. Section E—underground work: cables and stoneware culverts. Section F—transformers and switchboards. Section G—arc lamps, posts, and accessories. Section H—meters. Tenderers are at liberty to tender for either section, but not for part of a section. The ground plans of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after Wednesday, September 16, on payment of £2. 2s. for each copy, which sum will be refunded on the return of the specification, filled up with a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to the town clerk, Mr. R. Borrough Hopkins, at the Town Hall, Morley (Yorks), and be delivered on or before Wednesday, October 14.

RESULTS OF TENDERS.

Dundee.—The Gas Committee of the Town Council have accepted the offer of the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, Silvertown, to lay down india-rubber-covered electric cables in the Overgate, Wellgate, and Whitehall-street districts. The price is £718. 1s. 9d.

Glasgow.—Messrs William Ramsay and Co, electrical engineers, 11, Jamaica-street, have received the contract to fit the electric light on an extensive scale into the Liberal Club, Buchanan-street. The installation includes lighting of halls, dining-room, reading-room, card-room, billiard-room, smoke-room, staircases, etc.

Salford.—The Guardians received two tenders for the maintenance and repair of the telephones at the clerk's office and workhouse—one from Mr. J. G. Riddell, King-street, Manchester, who offered to do the work for £9 per year; and another from Mr. John Faulkner, Great Ducie street, Manchester, who quoted £9. 10s. per annum. The tender of Mr. Faulkner was accepted.

Shoreditch.—The Vestry have accepted the following tenders: The Electrical and General Engineering Company for wiring underground conveniences at £39. 7s 6d.; Messrs. Hemingway for Contract No. 6 at £442 (Messrs. Laing, Wharton, and Down having withdrawn their tender in consequence of the omission of an item of £100); and Messrs. Macfarlane and Co, for the supply of combined arc and incandescent lamp posts at £527.

Dortmund.—The figures of the tenders for the supply of engines, boilers, and dynamos for the town electricity works have been published, but not the name of the firm to whom the contract is to be given. A large number of German firms tendered, but as the tenderers specify the efficiency, consumption, etc., they propose, there is, strictly speaking, no "lowest tender," except in the case of the dynamos, for which the lowest tenders are those of the Helios Actien Gesellschaft.

BUSINESS NOTES.

Holywell.—The new line of telegraph from Holywell to Halkin was opened last week.

Whitefield (Gloucester).—It is proposed to establish telephonic communication in the town.

Direct Spanish Telegraph Company.—For the month of August the receipts were £2,038.

Sleaford.—In all probability the Kesteven and Grantham District Asylum will be lighted by electricity.

Willenhall.—The Council are going to introduce electric fire-calls and other improvements at the fire station at a cost of £224.

Oswestry.—The Town Council have decided to purchase an automatic electric motor pump for sewage work at a cost of about £250.

Belfast.—The Corporation have accepted the tender of Messrs. William Coates and Son for the fitting up of an installation of electric light in the gasworks.

Change of Address.—Messrs. Calvert and Co., electrical engineers, have removed from 24, Exchange-buildings, Manchester, to larger premises at 4, St. Mary-street.

Wigan.—The minutes of the Gas and Electric Light Committee were adopted at the meeting of the Town Council after some lengthy criticisms on the part of Mr. Fyans.

Rotherhithe.—The Vestry have accepted the tender of the Brush Electrical Engineering Company, Limited, amounting to £196. 12s. 6d., for the provision of electric wires to the new town hall.

Electric Club, Limited.—This Company has been formed, with a capital of £1,000 in £1 shares. Its object is to acquire and carry on the Electric Club, as now carried on at 44, King William-street, E.C.

Personal.—Mr. John C. Snell, the King's-road electric station engineer, has resigned his appointment under the St. Pancras Vestry, having been appointed borough electrical engineer of Sunderland.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending September 6 amounted to £1,212, as compared with £1,324 in the corresponding week of the previous year, being a decrease of £112.

Auto-Motor Express Company, Limited.—This Company, with a capital of £2,000 in £1 shares, has been formed to carry on the business of commission agents, shippers, carriers, etc., in all or any of their respective branches.

Dundee.—In the Town Council estimates for the current year, which were adopted at the last meeting, lighting is set down at £6,435, in place of £6,495, a saving of £60 being expected in the electric lighting of the High-street.

Boston.—The Town Council have approved the action of the Paving and Lighting Committee in authorising the expenditure of £25 in obtaining the opinion of an expert on the question of providing an electric light installation.

Carnarvon.—The Town Council have granted permission to the National Telephone Company to put up telephone poles in Mill-lane, Hole-in-the-Wall-street, and the Corporation yard, subject to the conditions of their usual agreements.

Digitized by Google

Johannesburg.—It is stated that the Government has sanctioned a scheme for providing the Rand with a comprehensive scheme of electric tramways for the purpose of connecting the city with some of the populous suburbs along the main reef.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending September 4 were £2,374. 0s. 2d., compared with £2,123. 2s. 10d. for the corresponding period of last year, being an increase of £250. 17s. 4d.

The French Congo.—The French Government is understood to have decided to establish a telegraph system in its Congo territories, and an engineer is to be sent out to make the necessary arrangements for setting up the line and organising the service.

Glasgow.—The Corporation Tramway Committee have resolved to recommend that the tramway manager and engineer should be sent to America to make further enquiries about electric motors. The Corporation have purchased the Govan and Ibrox Tramway for £7,500.

Epsom.—The Urban District Council have decided to engage Mr. Hawtayne, electrical engineer, to report upon the question of electric lighting for Epsom, with a view to obtaining from the Board of Trade a provisional order authorising the Council to light their district by electricity.

Price-List.—We have received from Mr. Arthur Cort, of 277, Camberwell New-road, London, his price list of red, grey, or black hard or flexible fibre in sheets, tubes, rods, washers, valves, etc., for electrical, mechanical, railways, tramways, carriage builders, and general engineering purposes.

City and South London Railway.—The returns for the week ended September 6 were £848, compared with £839 for the corresponding period of last year, being an increase of £9. The total receipts for the half-year 1896 were £9,181, compared with £8,508 last year, being an increase of £673.

Newport (I.W.).—The Town Council have decided to agree with the National Telephone Company to pay £9. 10s. per annum for a term of seven years for their providing and maintaining a telephone service from the waterworks to the town hall and sewerage works, independent of the exchange.

Portraits.—Under the title of "Men and Women of the Century," a collection of portraits by Mr. R. Lehmann is to be published by Geo. Bell and Sons. The facsimile work is to be done by the Swan Electric Engraving Company, and the collection includes the portraits of several engineers and men of science.

Westminster.—The system of electric lighting at the official residence of the First Lord of the Treasury in Downing-street is being extended. The electric light has been for some time in use in some of the principal apartments, but during the present recess the system will be made general throughout the establishment.

Blackpool.—The Council have made an alteration in the scale of charges, to take place from January 1, 1897, to the effect that all consumers over 10s. per quarter are to be charged 8d. per unit for an average consumption of one hour per day, and that for all current over and above the average only 2d. per unit will be charged.

Droitwich.—The question of adopting the electric light has started in the town. At the last meeting of the Town Council some opposition was made to the proposal to spend £3,000 on an extension of the gasworks on the ground of the possible adoption of electric lighting. The little cloud no bigger than a man's hand has appeared on the horizon.

Shoeburyness.—At a meeting of the Urban District Council a letter was received from Messrs. Alfred Dickenson and Co. saying that they had clients who were prepared to construct an electric tramway from Southend to Shoeburyness, and they asked if the Council would approve of it. It was agreed to reply that the Council would favourably consider the scheme.

Leatherhead.—Mr. Dearle has given notice to move at the next meeting of the Urban District Council, "That a memorial be presented by this Council to the Board of Trade applying for a provisional order under the Electric Lighting Act, 1882, to authorise this Council to supply electricity for any public or private purpose within the area of the urban district of Leatherhead."

Bristol.—Highbury Chapel and Redland Park Church are among the most recent of the many places of worship which have adopted the electric light. Additional machinery—part of the extension scheme in connection with which sanction to borrow £75,000 was recently obtained—will shortly be put down, and the committee will then be able to supply current for 34,000 incandescent lamps.

Outing.—The employés of the Incandescent Electric Lamp Company, Limited, of Hammersmith, had their annual outing on Saturday last. The party, numbering over 150, accompanied by the manager, Mr. C. J. Robertson, proceeded to Hastings by an early train. Dinner was served at the Central Hall, and after a most enjoyable day the party returned to town, reaching London shortly before 10 o'clock.

Dewsbury.—At the meeting of the Town Council Mr. W. Townsend asked if the Corporation electrical works were improving in regard to income, or whether, if there was a debit, it was gradually lessening. The Mayor said the statement of the electrician was that there was a debit for the half-year of £139, but the annual statement was expected to show that they were on the right side. It was agreed to extend the mains to Wilton-street.

Appointment Vacant.—The Electric Lighting Committee of the borough of Huddersfield are prepared to receive applications for the situation of working mechanical engineer in the electric supply station. Salary £2. 10s. per week. Applications must be sent to Mr. F. C. Lloyd, town clerk, at the Town Hall, not later than Monday, September 21, endorsed "Working Mechanical Engineer." Further particulars of the appointment appear in an advertisement in another column.

Girston.—Mr. Medhurst having reported upon the subject of supplying the district with electricity in conjunction with a refuse destructor, the District Council have decided that the scheme suggested by Mr. Medhurst be adopted, that the law clerk shall take steps to acquire an order from the Board of Trade and apply to the Local Government Board for sanction to borrow £25,000 to carry out the works, and also advertise for a site for the refuse destructor and works to supply electricity.

Tonbridge.—The Electric Lighting Committee have been empowered to obtain a report from a competent electrical engineer as to the requirements of the town at a cost not exceeding 20 guineas. At the meeting of the gas company, a considerable discussion took place as to the desirability of the company applying for a provisional order to enable them to supply electricity within their area, but the matter was allowed to remain over until it was seen what steps the Urban District Council take.

Yarmouth.—This year's statement of Corporation income and expenditure is considerably increased by the figures of the electric lighting department. The amount expended on the electricity works since they were begun to December 31 was £20,232. 0s. 10d. The receipts for the same period totalled up to £18,707. 12s., showing a difference of £1,524. 8s 10d. against the borough. For the year ended March 25 the revenue amounted to £1,914. 17s. 1d., and expenditure, without interest or sinking fund, £1,765. 9s. 7d.

Millet's Patent Motor Wheel and Cycle Company, Limited.—This Company has been started, with a capital of £100,000, to carry on business as manufacturers of and dealers in motors of every description, cycles, omnibuses, carts, wagons, vans, vehicles, ships, boats, launches, flying machines, and carriages of all kinds, and also all apparatus and implements and things for use in business, pleasure, or recreation, or any component parts thereof or accessories thereto, also as electricians, mechanical engineers, etc.

Colwyn Bay.—A letter was read at the meeting of the Colwyn Bay and Colwyn Urban District Council from Messrs. Dickinson and Co., Birmingham, as to the opinion of the Council with reference to the construction of an electric tramway between Colwyn Bay and Llandudno. Mr. George Bevan moved, the Chairman seconded, and it was carried, that the Council are in favour of such a project, and calling attention to the fact that the power of supplying electricity in the district is now vested in the Council.

Liverpool.—Mr. Charles Rettie of Geraint-street, writes to the *Liverpool Mercury* asking why the Corporation do not reduce the price of electricity to 4d. all round. Since the Corporation have taken over the electric supply company's undertaking, both the supply and contract department, they have reduced the price per unit from 7½d. to 7d., and for large consumers taking over 1,000 units to 4d., and the meter rent has been, or will be, reduced from 2s. per month to 1s.; but Mr. Rettie thinks everybody ought to be treated alike

Warrington.—At the meeting of the Town Council Councillor Heaton, in moving the confirmation of the minutes of the Gas Committee, remarked that it would be seen that the chairman had been requested to bring the question of electric lighting before the General Purposes Committee, and he had no doubt he would do so. Councillor Bennett said he cordially congratulated the committee upon their prompt acceptance of the suggestion he made at a recent meeting with regard to electric lighting. He hoped that before very long they would have a very desirable improvement in Warrington in that respect.

Presentation.—On Monday evening, the 31st ult., an interesting gathering took place at Wolverhampton, the occasion being a presentation to Mr. William Bulloch, C.A., accountant to the Electric Construction Company, in honour of his approaching wedding. The present consisted of a handsome silver tea service and salver, and in a few well-chosen remarks, Mr. A. B. Blackburn, manager, referred to the good feeling existing among the officials of the company, and asked Mr. Bulloch to accept of the gift with the best wishes of the subscribers, which included the technical and commercial staff both at Wolverhampton and London.

Birkenhead.—The Finance Committee of the Corporation have considered the subject of the supply of electricity in the borough. It is expected that the work of laying wires and erecting electric light generating stations will be completed by the middle of the month, when the current will be available for consumers in the central districts of that town, where at present mains have only been laid. It has been arranged to introduce the light as soon as possible into the town hall. The standard of energy in the distributing mains has been fixed at 230 volts, and consumers will be charged according to the actual quantity of energy supplied after the rate of 6d. for every unit.

Shoreditch.—The Lighting Committee of the Vestry having considered the three tenders for wiring underground conveniences recommended that the tender of the Electrical and General Engineering Company, at £39. 7s. 6d., should be accepted. This was agreed to. Messrs. Laing, Wharton, and Down having omitted the cost of mains to the motors in their tender of £428 9s. 6d. under Contract 6, wished to withdraw unless a variation in the specification was allowed. As this would mean £100 extra, it was decided to accept the next lowest tender, of Messrs. Hemingway at £442. Three tenders were sent in for the supply of combined arc and incandescent lamp posts, and that of Messrs. Macfarlane, at £527, was accepted.

Digitized by Google

Niagara.—The first long-distance transmission of electrical current from Niagara Falls is to be started early in November, the current being conveyed to Buffalo, a distance of 20 miles, where it will be used for traction and other purposes. The voltage is to be 11,000, and transformers are being completed at either end at Niagara. The current is 2,200 volts, but it will be increased, while at the Buffalo end it will be stepped down from 11,000 to 100 volts. Part will be used for traction work at 550 volts The first instalment of power to be transmitted is 1,000 h p., and this will be used on the tramways of Buffalo, but the pole line for the conductors has a capacity for 40,000 h.p.

Chester.—The laying of the electric light cables is going on satisfactorily. The cable has already been put down on both sides of Watergate-street and Bridge-street and one side of Eastgate-street. The next street to be dealt with is Northgate-street. The main distribution-box will be fixed near the market, and we hear it is intended, after the first installation, to lay a feeder as far as the boundary of the compulsory area, which extends to the top of St. John-street. The lighting station is rapidly nearing completion. The whole of the roof is on the engine-house, boiler-houses, battery-room, and offices. Two of Messrs. Babcock and Wilcox's boilers have already been put in their places. The chimney has reached half its proposed height, which will be 140ft

Aberdeen.—A memorial signed by all the traders in the portion of George-street in which the electric mains are laid has been presented to the Town Council requesting that the thoroughfare be lighted by means of electric lamps. The city is now in direct communication by telephone with practically the whole United Kingdom, excepting Inverness and northward. The trunk wires all over Scotland will, after December 19, be wrought entirely by the State, although they have actually been its property since April 4. The portion of the trunk wire from Aberdeen to Glasgow is the old trunk line, but from Glasgow to London a special line has been constructed by Government. The wires are of copper, and weigh 800lb. to the mile, and they are worked on the loop principle.

New Swindon.—The following letter from Messrs. Eastlake, Limited, electrical engineers, of Parliament street, Westminster, S.W., was read at the Urban District Council meeting : "Swindon New Town Electric Lighting Order.—Dear Sir,—With reference to the above, we are prepared to make a proposal to your Council to take over the provisional order they have obtained for a term of years. We are further prepared to enter into an arrangement with the Council for the destruction of the town refuse should this be desired. We should be obliged if you will place this communication before your Council, and inform us whether they are disposed to entertain such a proposal, when we should be glad to enter fully into the matter with them " The letter was referred to the Electrical Lighting Committee.

Sale.—Letters were read at the Urban Council meeting from Messrs. Andrew and Butterworth respecting the proposed electric tramway from Stretford, *viâ* Sale, to Peel Causeway, and also from the Manchester Carriage Company, asking the opinion and assistance of the Council for a tramway to and from the same place to be worked by horses or electricity. A long discussion followed, and it was decided to acknowledge the receipt of the letters, and to reply that the Council were disposed to sanction the tramway consistent with the interest of the ratepayers being safeguarded. The matter was re-referred to a special committee of the above Council which was to meet and receive deputations from the promoters of both schemes, and after considering the matter to report to the next Council.

Bury.—The Electric Lighting Committee have resolved not to grant the application of Messrs. Siemens for an extension of the time for the completion of their contract, and notice has been given to them that unless the work is completed in the time stated in the contract the penalty clause will be enforced. The distributing mains are to be extended from Clough-street up Stanley-street and Water-street to the bottom of Walmersley-road. The tender of Chamberlain and Hookham for meters has been accepted. The Mayor, the Chairman, Alderman Parks, and Councillor Collinge have been appointed a sub-committee to make proper arrangements for a formal opening of the electric light installation. It is proposed to light the large lamp in the Market-place and certain other lamps with electricity.

Tunbridge Wells.—The vicar of St. Mark's, the Rev. Dr. Townsend, writes as follows : "When I first advocated the use of the electric light in St. Mark's one of the advantages suggested was economy ; this forecast seems likely to hold good. I have seen the electric light account for the quarter ending June 29, 1896, and I find that it is considerably less than the gas account for the same quarter in 1895. The electric light stands at £4. 12s., while the gas cost us about £5. 12s. This is a large percentage of difference, and if it holds good in the other quarters a decided saving of expense is likely to ensue." It may be added that not only is the church better lighted, but the congregation enjoy the comfort of a purer atmosphere at the services, so that these advantages must be added to the economy.

Croydon.—The Corporation on Monday night brought its new electric lighting works into use for the first time the municipal buildings, with the clock tower, being illuminated by electricity. The town hall contains 1,000 lights of 16 c.p. each. The experiment was an unqualified success. It is expected that electric lighting in the borough will be general by the end of next year. The works are rapidly approaching completion. The flues at present are connected with a temporary iron shaft, and it was, we understand, contemplated to retain this temporary shaft until the destructor scheme had developed, and then raise a permanent shaft which might answer for the two. It has, however, now been decided to put up a separate shaft for these works. The concrete bottom has been laid in, and the flues will be extended as this is raised.

Company Receipts in America.—The Edison Electric Illuminating Company of Brooklyn report gross earnings for July of 59,018dol., an increase of 9,918dol. as compared with the same month of last year, and net 24 138dol., an increase of 5,432dol For the seven months ended July 31 the gross earnings were 462,430dol., an increase of 161,608dol. as compared with corresponding period of last year, and net 205,274dol., an increase of 78,719dol. The Edison Electric Illuminating Company of New York report gross earnings for July of 156 891dol., an increase of 21,197dol. as compared with the same month of last year, and net 67,270dol., an increase of 8,736dol. For the seven months ended July 31 the gross earnings were 1,262,795dol, an increase of 111,154dol. as compared with the corresponding period of last year, and net 611,803dol., an increase of 62,267dol.

Crewe.—At a meeting of the Town Council the Health Committee submitted a report advising that the isolation hospital should be lighted by electric light. It was pointed out that 28 beds in the hospital were apportioned in the various wards on the basis of 2,000 cubic feet to each patient, assuming that gas was the illuminant used ; but with electric lighting substituted for gas, this amount might very well be reduced to 1,200 cubic feet, in which case the accommodation would be increased from 28 to 45 or 52 beds, thus obviating the necessity of future extension for many years. The difference in the cost would be an increase of £17. 18s. 6d. per annum, this including the repayments of principal and interest on a loan for the provision of the necessary apparatus, including engine, dynamo, and installation of 104 lights. The recommendation of the committee was adopted.

Rangoon.—The plant for the electric lighting of the Jubilee Hall arrived the last week in July. The machinery and fittings are from Crompton and Co., London and Chelmsford. The plant consists of two of Crompton's compound dynamos, driven by separate engines of Marshall and Co.'s latest designs. Each dynamo will run one-half of the light, thus providing against a total extinction of the lights. The electroliers and all fittings are handsome and substantial, and are from the firm of Edison and Swan. London stage-lighting apparatus of the most recent design, as adopted in the London theatres, has been supplied by Crompton and Co. The management of the work will be undertaken by Mr. D. Coath, Crompton and Co.'s agent in Rangoon, who gives his own services and provides the necessary skilled labour for fitting up the installation free of charge as his contribution to the Jubilee Hall.

Dudley.—A sub-committee appointed to consider the whole question of public lighting have resolved as follows : "Your committee are unanimously of opinion that a provisional order should be applied for by the Town Council enabling them to supply electricity for lighting and other borough purposes as soon as practicable, and they believe, especially considering the advantageous terms upon which capital can now be raised, the installation can be made a commercial success. They feel, however, that the responsibility of taking the necessary steps to carry out this recommendation, costing as it is estimated to do £25,000 or thereabouts, should be taken by the Council and shared by every member thereof, and they therefore advise that the Council should themselves appoint a committee, not exceeding 10 in number, who should not be shareholders in the Dudley Gas Company, and who have, where possible, some practical acquaintance with electric work and machinery, such committee to consider the subject fully and report definitely to the Council at their October meeting."

Hammersmith.—The Vestry have received 130 applications for the position of resident engineer in connection with the electric lighting works. The applications have been referred to the Electric Lighting Committee with instructions to select six to appear before the Vestry. The Electric Lighting Committee reported as follows : "That having received a letter from Messrs. Leslie and Co., stating that they were unable to complete their contract in the time specified if the glazed fireclay is used for the plinth to the chimney shaft, as they found it would be impossible to get this made under three months, and suggesting that the substitution of Bramley Fall stone for the glazed firebrick, which would effect a saving of 1s. 4d. per cube foot (about £60), we have authorised the substitution of Bramley Fall stone for the glazed fireclay in the moulded plinth course. The difference to be adjusted on completion. That we have given instructions for certain necessary statutory notices to be served upon the Postmaster-General, the London County Council, and the railway, tramway, gas, water, and telephone companies, in accordance with the provisions of the electric lighting order."

Babcock and Wilcox, Limited.—The report of the directors for the year ending June 30, to be submitted to the general meeting to-day (Friday), states that the accounts show that the profit during the year amounts to £72,446. From this amount £20,000 has been written off purchase of business account, leaving £52,446, which, with £4,831 brought forward, makes a balance of £57,277. From this sum is deducted the interim dividend for the half-year to December 31 at the rate of 6 per cent. per annum on the preference shares and 5 per cent. for the first six months of the financial year on the ordinary shares, amounting to £10,000, leaving £47,277, from which the directors recommend that the following dividends be paid for the half-year ended June 30—namely, at the rate of 6 per cent. per annum on the preference shares (subject to income tax), absorbing £3,000, and 10 per cent,

Digitized by Google

for the second half-year on the ordinary shares (free of income tax), taking £14,000; placing to a reserve fund £25,000, and leaving a balance of £5,277 to be carried forward. Owing to increase of business, it has been found necessary to provide larger works, and for this purpose ground has been bought at Renfrew, where suitable works are being erected which, it is expected, will be completed within the next two months.

Salford.—The Electric Light Sub-Committee are preparing an approximate estimate of the cost of providing an electric light installation for the town hall, and also an estimate of the difference in cost of lighting by the electric current and by gas for one year. At a meeting of the Parliamentary and Public Trusts Committee a letter was read with reference to an application by the Manchester Carriage and Tramways Company for a double line of tramways in Eccles New-road to Weaste, and a further letter from Messrs. Brett, Hamilton, and Tarbolton, on behalf of the company, with reference to the construction of tramlines in Cross-lane and Trafford-road, in which they suggested that the company might apply for the requisite powers and allow the Corporation to carry out the work. The committee resolved that whilst thinking it desirable to accede to the request of the tramways company, at the same time they deemed it wise to make application for the necessary powers themselves, and recommended the Council to instruct the town clerk to make application to Parliament during the ensuing session for a provisional order empowering the Council to carry out the necessary works. The following were appointed a sub-committee to wait upon the directors of the tramways company and arrange all matters of detail: the Mayor, Aldermen Jenkins B. Robinson, W. Robinson, and Councillor Ollier.

Folkestone.—At the Town Council meeting Mr. Moat read the preliminary report of Dr. Hopkinson upon the draft agreement between Mr. Hopkins and the Corporation The general tenor of it was that the terms proposed were fair and reasonable on both sides, and, in fact, rather advantageous to the town, as compared with other towns, but he asked for further information as to the area, etc., to be lighted. Councillor Pursey said he did not think they were really in a position to deal with the report, as it was a document which would want a good deal of overhauling. He was not at all satisfied with the way in which it had been submitted to Dr. Hopkinson. He always thought that the draft agreement was to be first submitted to the Corporation, but it had not been. In the first place, there was no provision as to the system of electric lighting, and the machinery that was to be put in, and as they, as a corporation, were to have the right to purchase at a stated period, they ought to know what they would have to purchase. There were many other really important points that ought to be introduced. He moved that it be submitted to a committee, consisting of Councillors Tolputt, Penfold, Baker, himself, Councillor Vaughan, and the Mayor. Councillor Harrison seconded. Councillor Jones moved as an amendment that it be a committee of the whole Corporation, and Mr. Pursey assenting to this, it was carried.

Cheltenham.—The question of the proposed electric tramway has again been before the Street and Highway Committee, and they have resolved that the route be from the Midland Station, along Queen's-road, Lansdown-place, Bayshill-road, St. George's-parade, St. George's-place, St. James's-parade, St. James's-square, Ambrose-street, St. George's-street, St. Margaret's-road to North-place, North street to gas offices, Albion-street to Portland-street, Portland-street to Evesham House, thence to Prestbury-road, and along Prestbury-road to the borough boundary; also that the gauge of the tramlines be the standard gauge of 4ft. 8½in. At a meeting of the Lighting Committee the borough surveyor submitted plans of two alternative arrangements for lighting the Promenade and High street with arc lamps, one requiring 56 lamps and the other 62; also a design for suspending the lamps in the Promenade by means of pairs of pillars, 37ft. high, of steel tube with ornamental cast-iron base, and a chain or wire rope at any desired height between 16ft. and 22ft., the cost of which would be about £25 per lamp; and that 11 lamps would be required in the Promenade if ordinary lighting was adopted. The committee resolved that for a commencement the number of arc lamps for the Promenade and High-street be 58, and that the borough surveyor be instructed to obtain a pattern of the pillars for the Promenade.

Burnley.—At a meeting of the Gas and Electric Lighting Committee the electrical engineer reported the result of enquiries made by him with respect to extending the electric main in Yorkshire-street. It was resolved that, subject to the approval of the Council, the main in Yorkshire-street be extended to Plumbe-street, at an estimated cost of £200, and that, in the event of the trustees of the Fulledge Chapel undertaking to use the electric light in connection with their schools and chapel, the electrical engineer be authorised to further extend the main to Fulledge Chapel, at an additional cost of £100. The price of electrical energy for public purposes was reduced to 3d. per unit. At the meeting of the Town Council Alderman Parkinson said he thought the committee were too hard upon applicants before consenting to extend their mains. He believed they required a guarantee of a turnover representing 20 per cent. of the total outlay. He thought that was too much to ask. Alderman Sutcliffe said it was the outlay on the cable only, not the works. The Mayor did not think it would be wise to deviate from the system upon which they had hitherto acted. The salvation of their works, in making them a paying concern, had been the limiting of their cables to a somewhat confined area. If they were to branch out indiscriminately in any direction and to have, perhaps, a very few customers topping a cable which they might lay, the profit would soon turn into a loss.

Bradford.—At the meeting of the Town Council, Mr. W. C. Dixon (chairman of the Gas and Electricity Supply Committee) moved the adoption of the minutes of that committee. The minutes included resolutions for the extension of electricity cables up Little Horton-lane, Church-bank, and Barkerend-road, at a total cost of £850; the reduction of the charge for electricity supplied for motive power from 3½d. to 2½d. per unit from January 1 next; and advancing the salary of Mr. W. Jones, mechanical engineer in the electricity department, from £143 to £170. Mr. Dixon said the electricity department was making as rapid progress as the Corporation could desire. The three-wire system had been completed practically throughout the borough. The buildings were as far advanced as had been expected, and one of the new engines was already being put into its place. The two new boilers were in Bradford waiting to be delivered, and would be put in position as soon as possible. There was a trade profit in connection with the electricity department for the half-year of £3,578, as against £3,176 last year, or 4·24 per cent., against 4·73. There was a net profit, after deducting interest and sinking fund, of £1,007, against £986 last year, or 1·19 per cent, against 1·47 per cent. The capital outlay amounted to £84,351, against £67,112 last year. He had to report a substantial increase of 35,954 Board of Trade units. The total net revenue from the gas, chemical, and electricity works to be handed over to the Finance Committee for the reduction of the rates was £8,557, equal to a saving of 4d. in the pound for the half-year. The minutes were adopted. The question of applying for power to construct tramways to Great Horton and Bolton road was deferred for further consideration.

Eccles.—The report of the proceedings of the Electric Lighting Committee of the Town Council has recently been issued. It contains a letter from the Local Government Board in which they state that, after consulting the report made by Mr. Willcocks, who held an enquiry into the application of the Council to borrow £20,000 for the electric lighting of the borough, "they are advised that the scheme is not altogether satisfactory, and in particular that, in a compact district like Eccles, a continuous current with a low pressure should be used, and not an alternating current with high pressure and transformers as proposed, inasmuch as under the latter system accumulators cannot be used, and heavy expense would be incurred in keeping the dynamos running all day. The proposal of the Town Council to avoid this expense by cutting off electricity for eight hours every day would result in a very serious inconvenience to those who may wish to use electricity for other than lighting purposes. Further, the Board are advised that the land proposed as the site for the generating station is too small for the purpose, and that the stipulation in the covenant on the land as to the carrying on of any business which was, or could, and might be deemed a public nuisance or a private annoyance or inconvenience to the neighbourhood might very probably lead to litigation after the works had been set up. Moreover, the Board learns that there is considerable opposition to the scheme, and they understand that there is not now a majority of the Town Council themselves in favour of it. Under these circumstances the Board are not prepared to comply with the application of the Council." An offer from Edmundson's, Limited, to take over and carry out the electric lighting order obtained by the late Local Board has been referred to the Council to deal with.

Bury St. Edmunds.—At the Town Council meeting Alderman Lake again asked the Town Clerk (Mr. C. E. Salmon) as to whether it was probable the Local Government Board would sanction the formation of a private company, having for its object the indemnity of the Council for the period of 20 years against loss from supplying the borough with the electric light, the company to receive all profits which might be made during the same period. The Town Clerk remarked that the question was of such a novel character that he thought it best to look into the matter before giving an answer. He had communicated with his parliamentary agent (Mr. E. E. Baker), who, in answering from 22, Great George-street, Westminster, wrote: "I certainly never heard of such a proposal before as that suggested in your letter, and very much doubt whether the Local Government Board would sanction it, but as the Corporation are applying for an electric lighting order, the Board of Trade might be asked to insert clauses to carry out the proposal, and if they agreed probably the Local Government Board would also agree. The scheme would be quite unworkable unless the Corporation have an absolutely free hand with regard to the working of the undertaking as to price to be charged." Alderman Lake felt confident that, could such an arrangement have been made as that which Alderman Gough and himself were prepared to stand by, the ratepayers would have complained when they found the profits were going into the pockets of guarantors. Alderman Gough anticipated that ultimately there would be a handsome profit from the adoption of the electric light, although it might not be realised during the first few years. Personally he regretted his offer to become a guarantor could not be accepted.

Catalogues.—We have received from Mr. A. H. Avery, of Tenterden, his catalogue of electrical apparatus and appliances. Many of the articles in the catalogue have been designed to suit the wants of amateurs, and there is at least one speciality—namely, static electromotors. Of these it says "there is no complete circuit through them, and they consequently take no current, working on the principle of mutual repulsion." It is to be presumed that by no current is meant so little current as not to be easily measurable in the ordinary way. It is understood that Mr. Avery suggests that these motors are more than mere toys, and may "find a useful application in such establishments as paper factories, where at times great trouble is experienced

Digitized by Google

from static discharges," since "by the use of a static motor these discharges can be transformed into mechanical energy and used for ventilating purposes, etc." If anyone would like to try to run a small fan with one of these, it can be done for from 15s. to 30s, according to size. Another of Mr. Avery's special articles is a pole-finding paper. Mr. Avery says this is extremely sensitive and cannot give inaccurate results We have not had the pleasure of trying it, but if that is so it is decidedly superior to some specimens we have seen of German manufacture, with which it would be quite possible for the ignorant amateur to make mistakes. Mr. Avery claims a high quality for all his goods.—We have also received the 1896 price list of the Newton Electrical Works at Taunton. The special production of the works is, of course, the "Taunton" dynamo. This is listed for 100 volts and 135 volts on the first two pages. Direct-coupled engines and dynamos follow, and then come motors, switches, and transformers (alternating and continuous current). There are excellent illustrations, including one of the switchboard supplied to the Bristol Corporation station, and diagrams and descriptions relating to the fixing of motors with their starting switches and regulating and reversing boxes.—We also have to acknowledge the receipt of a bound electrical catalogue from Mr. G. Braulik, 218, Upper Thames-street, a review of which will appear next week.

Hastings.—The Roads Committee reported at the meeting of the Town Council that they had received a communication from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, stating that the company's reasons for placing the proposed transformer-pit under the public pavement opposite the Claremont Library (the plans for which were, on the committee's recommendation, disapproved at the last Council meeting, the site for the proposed pit being in their opinion an unsuitable one) were that their mains ran past the spot, and that if the pit were placed on the other side of the road their mains would have to be run across the road to the transformer, and then back again to their present position, which would entail extra expense and cause inconvenience by opening the road. The committee, under the circumstances, now recommended that the plan be approved subject to the work being carried out to the satisfaction of the borough engineer, and to the company giving the usual undertaking not to remove the cover of the pit except between the hours of 10 p.m. and 9 a.m, unless in case of actual emergency. The Roads Committee had also received notice from the company of their intention (*a*) to carry a high-tension concentric $^{7}/_{16}$ cable from an existing box on the east side of the junction of London-road with Norman road, to a point opposite 76, Norman-road; (*b*) to carry a pair of $^{7}/_{16}$ low-tension cables from a point westward of the St. Leonards Mechanics' Institution premises to the point opposite 76, Norman-road aforesaid; and (*c*) to place a cast-iron box, 2ft. by 1ft. 6in., with pavement frame and cover in the pavement in connection with the said mains, in accordance with a plan submitted, and stating that the cables would be run in 2¼in. pipes, laid 18in. under the pavement, and 18in. from the kerb. The committee recommended that this plan be approved, subject to the works being carried out to the satisfaction of the borough engineer, to the company giving the usual undertaking not to remove the cover of the box except between the hours of 10 p.m. and 9 a.m., unless in case of actual emergency, and to the mains being laid at a depth of not less than 30in. at the point where the same cross from the north to the south side of the road opposite the St. Leonards Mechanics' Institution premises. The recommendations were adopted.

Blackburn.—A meeting of the shareholders of the Blackburn Corporation Tramways Company, Limited, has been held to consider a letter from the town clerk of Blackburn with regard to the adoption of electric traction. The letter was to the effect that the Corporation had recently authorised an application for further capital for largely extending their electric lighting works, and in the course of the next year or two probably an additional expenditure of £15,000 would be incurred. The letter further asked that the company would say now whether they would require electricity, and also recommended to the company the adoption of the overhead system. The chairman, in dealing with the two-horse sections of the line—viz., the Preston New-road and Witton lines—directed the attention of the shareholders to the circulars which had been sent to them, showing the comparison of cost between electric and horse power traction on the two sections mentioned. The cost per mile for the 93,892 miles run on the horse sections was 5·95d., whilst it had been calculated that electric traction would cost 3·0d. per mile for the same number of miles, or if increased to 160,000 miles per year, 2½d. per mile. The latter distance, however, they would not be able to reach for many years to come. The Corporation would, if the company so desired, maintain the overhead line for £100 a year. As to the actual working on other lines, repairs and renewals of motors working under cars for 180 000 miles were calculated to cost £150 a year. He (the chairman) had had the opinions of two electrical experts on the subject, and one of them stated that he would contract to do the work for the amount named. An important consideration in favour of electricity was the fact that an electric car would carry 48 passengers, compared to 32 per horse car, which would prove a sure source of income. After considerable discussion, a resolution was passed by a large majority, agreeing to electric power being adopted on the Preston New-road and Witton sections, provided that suitable terms could be made with the Corporation for the supply of the same, the terms to be satisfactory to the Board. The minutes of the Gas Committee, which were adopted at the Town Council meeting, stated that the electrical engineer had reported that in consequence of the extension of the electric lighting installation, it was now necessary to appoint another assistant electrical engineer and also another engine and dynamo attendant, and that it had been resolved that it be an instruction to the town clerk to advertise for an assistant electrical engineer at a salary of £125 per annum, and to submit the applications received to the next meeting of this committee; also that the electrical engineer be authorised to engage an engine and dynamo attendant at the same rate of wages as are paid to the present one.

Colchester.—Colonel Ord Hasted, R.E., one of the Local Government Board inspectors, has held an enquiry in reference to the proposal of the Corporation to borrow £15,000 for purposes of electric lighting. The Town Clerk said he had particulars of the voting during the history of the whole matter which had led up to the application, so that the inspector would see that if there were any opposition it had only arisen recently and in a particular manner. The Bill received the Royal assent on June 9, 1893, the order slightly predating it. The area over which the Bill made the extension of electric lighting compulsory was North-hill, Head-street, and High-street from the top of North-hill to the end of St. Nicholas-street. The Corporation proposed to do rather more than that. There had been no proposal for a company, owing probably to the stringent regulations with which the Corporation hampered the possible formation. There was a proposal by Messrs. Christie to undertake the works on certain terms out of which they considered they could make a fair profit, but the committee considered that the works should be under the control of the authority. The Borough Surveyor produced and explained the plans for the electric lighting station. The buildings were plain, but substantial Mr Massey, the engineer appointed by the Electric Light Committee, gave details as to the machinery, and the cost, which had been ascertained from the actual tenders, and was not a mere estimate. The system it was proposed to employ was the low-tension three-wire system, worked with a current of from 225 to 240 volts. Provision was made for increasing the normal capacity for an hour. The engines, which would be three in number, each being 180 h.p., would couple direct on to the dynamos. The station was rather larger than the present requirements necessitated, in order to provide for extensions. They were providing machinery for 4,000 lights, but the switchboard and buildings were provided for a larger number. Street-lighting could only in the early stage be undertaken at a loss, and the Corporation had decided to drop it for the present, but it could be taken up at any time. To do street-lighting the machinery would have to be added to. The mains were capable of taking more current than it was at present proposed to use, in order to provide for future extensions. The feeders were laid down on such a system that all gas explosions owing to their presence would be impossible. They were providing mains for 4,360 yards of streets. Tenders were obtained for carrying out the work (with the exception of the buildings) from four of the best firms in England, and after most careful consideration it had been decided to place the order provisionally in the hands of the Electric Construction Corporation, of Wolverhampton, whose estimate the inspector had before him. The £15 000 includes the cost of buildings £3 000, land £600, and the remainder is for electric plant. The cost of laying the mains is included.

Lynn.—The minutes of the Urban Sanitary Committee, which were adopted at the last meeting of the Town Council, stated that the following communication and other subsequent letters relating thereto from Messrs. J. McLaren and S. L. Skevens with reference to lighting the borough by electricity had been received: "To the Mayor and Corporation of the Borough of King's Lynn.—Whereas it has been decided by the Corporation of the borough of King's Lynn to apply for powers to enable them to light the town by electricity, we, the undersigned, respectfully beg to submit for your consideration a scheme for carrying the same into effect. It will be understood that the plan we desire to bring under your notice will be considered only in the event of your determining, on pecuniary or other grounds, not to proceed with the work directly through the medium of your corporate powers. We are fully assured that the introduction of electricity on a large scale, such as is proposed, would be most beneficial to the traders and public generally, and would be largely employed by them both as an illuminant and motive power. Our plan broadly and generally described would be to form a company with a capital of, say, £———, the said company to take over and exercise, on lease or otherwise, the powers vested in the Corporation, the company to be in the position of lessee of the Corporation. The Corporation would not be called upon to guarantee or be responsible for any portion of the capital, and would have the option of purchase on the expiration of the lease granted by the Corporation to the proposed company. The work would be carried out under the superintendence of a duly qualified electrical engineer, Mr. J. McLaren, resident engineer at Sandringham, who is prepared to produce plans, specifications, and estimates, the same to be submitted to the Corporation for their approval and assent. We also respectfully beg to suggest that as soon as the Corporation shall have obtained the necessary powers the matter should be thoroughly investigated and a decision arrived at as to the best course of procedure, in order that the public may enjoy at as early a period as possible the advantages of the new illuminant. The erection of the necessary works and the laying of such an installation would necessarily take some months to complete, and all should be in perfect readiness for turning on the current into the street lamps on the expiration of the contract with the gas company. We believe the above scheme broadly and generally described will

Digitized by Google

commend itself to the majority of the inhabitants of this borough, and would materially assist the Corporation in their efforts to successfully introduce electric lighting. We should require of the Corporation that they grant us such rights and privileges as would ensure the successful carrying out of the scheme, and secure to the shareholders the profits arising from the same according to the terms agreed upon.—J. McLaren, S. L. Skevens." The borough surveyor has been instructed to make enquiries and obtain information from other towns where electric lighting has been introduced and report thereon at a future meeting; in the meantime Messrs McLaren and Skevens have been informed that the subject of their letter is under consideration.

PROVISIONAL PATENTS, 1896.

August 31.

19207. Improvements in starting speed-regulating, reversing, stopping, and steering mechanism for mechanically propelled vehicles. Ernest John Clubbe, Alfred William Southey, and the Electric Motive Power Company, Limited, 55, Chancery-lane, London.

19218. Manufacture or production of chemical products by electrolysis. Emil Joseph Constam and Arthur von Hansen, 46, Lincoln's-inn-fields, London.

September 1.

19290. Improvements in or relating to electrical furnaces. Alfred Julius Boult, 111, Hatton-garden, London. (Octave Patin, France.)

19301. Improvements in storage batteries. Albert Preiss, 55, Chancery-lane, London.

19303. Improvements in electromagnets. Theodore McKenna, 17, Basinghall-street, London. (Electric Selector and Signal Company, United States) (Complete specification.)

19304. Improvements in electric selectors and adaptions thereof and in transmitters therefor. Theodore McKenna, 17, Basinghall-street, London. (Electric Selector and Signal Company, United States.) (Complete specification.)

19305. Improvements in electrical selecting instruments. Theodore McKenna, 17, Basinghall-street, London. (John Mowe Drysdale, United States.) (Complete specification.)

19308. Improvements in utilising the residual products obtained in the working of certain kinds of voltaic batteries. William Walker, jun., Frank Richard Wilkins, Jabez Lones, and Joseph Lones, 7, Staple-inn, London.

19316. Improvements in electric lamps. Louis Andrews Jackson and Acme Electric Lamp Company, 53, Chancery-lane, London.

September 2.

19396. A new or improved combined electric lamp and walking-stick. Joseph David Lawrence, 33, Chancery-lane, London.

19399. Improvements connected with the electrical coating of tubes, rods, and the like, and apparatus therefor. William Stepney Rawson, 21, Greycoat-gardens, London.

19415. Improvements in or connected with electric railways. Frederick Carleton Esmond, Norfolk House, Norfolk-street, London.

September 3.

19455. Improvements in automatic switches and safeguards for electric traction systems. Silvanus Phillips Thompson and Miles Walker Morland, Chislett road, West Hampstead, London.

19456. An electric traction system. Silvanus Phillips Thompson and Miles Walker Morland, Chislett-road, West Hampstead, London. (Complete specification.)

19469. A means of surrounding electric or other lights with a vessel or lining of glass or other material containing liquids. Edward John Macready, 39, Hampden-street, Higher Tranmere, Cheshire.

19501. Improvements in electric light conduits Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

19505. Improved methods and apparatus for electro-thermally treating materials. Hudson Maxim, 45, Southampton-buildings, Chancery-lane, London.

19507. Improvements in electrical arc lamps. Hans Carl Madsen, 65, Chancery-lane, London. (Complete specification.)

19528. Improvements in dynamo-electric machines and electric motors. Sidney Augustus Nash, 47, Lincoln's inn-fields London.

September 4.

19558. Improvements in printing telegraph instruments. Emile Michel Denis André, 47, Lincoln's-inn fields, London.

19583. Automatic closing telegraphic key. James Arthur Coleman, 89, Chancery-lane, London.

September 5.

19638. Improvements in electrical indicators. Isaac Hardy Parsons, 21, Narborough-road, Leicester.

19639. An improved mode of electrical gas lighting. Annibal Légé, 31, Kirby-street, Hatton-garden, London.

19650. Improvements in insulators. Thomas Blankinsop and Joseph Wilson Brown, 89, Chancery-lane, London.

19660. Improvements in or relating to apparatus for supplying a certain definite amount of electric current (for lighting or other purposes) on prepayment. William Dobson Watson, 4, St. Anne's-square, Manchester.

19664. Improvements in glass globes or shades for electric, gas, or other lights. Sowerby's Ellison Glass Works, Limited, 19, the Arcade, Barnsley.

19693. An improved electric switch for certain useful purposes. Walter Charles Bersey, Ernest Francis Moy, and Ernest F. Moy, Limited, 433, Strand, London.

SPECIFICATIONS PUBLISHED.

1895.

13164. Dynamos. Wise. (Maschinenfabrik Oerlikon.) (Amended.)

15445. Step-by-step printing telegraphs. Steljes.

16659. Electric railways. Belfield. (Foreign Electric Traction Company.)

17525. Electrolytical manufacture of bleaching liquid. Kellner.

19027. Electric metering apparatus. Wise. (Barstow.)

20237. Electric safety fuses. The Edison and Swan United Electric Light Company, Limited, and Proctor.

21543. Apparatus for transforming continuous electric currents into alternating currents. Abel. (La Société Anonyme pour la transmission de la force par l'Electricité.)

1896.

3910. Magnetic regulator for the carbons of arc lamps. Klostermann.

4944. Electric arc lamp carbon and apparatus for the manufacture of the same. Lorrain. (Foote.)

8382. Automatic circuit breakers for use in electric tramcars or other electrically-propelled vehicles. Devonshire. (Potter.)

14462. Systems of electrical distribution. Boult. (Scott and Janney.)

15102. Method of winding armatures for multipolar continuous-current dynamo-electric machines and electromotors. Royce and Claremont.

NOTES.

Publication Received.—We have just received the *Bulletin* of the University of Wisconsin containing Mr. Ford's tests of American transformers. We hope shortly to refer further to the subject.

Belfast Mechanical Engineers.—The members of the Belfast Mechanical and Engineering Association, at the invitation of Mr. Stelfox, paid a visit to the Belfast Corporation gasworks on Saturday last and examined the working of the "water-gas" plant there.

Motorcarts.—It is stated that the Motorcar Club propose to celebrate the coming in force of the Locomotives Act on November 14 by a procession of motorcarts to Brighton and back. There are, however, several reasons why it is probable that the procession will not be a very great affair.

Personal.—The post of secretary to the Institution of Engineers and Shipbuilders in Scotland, which has been held by Mr. W. D. Millar for 25 years, but who is now retiring, has been secured by Mr. Edward H. Parker, from the experimental department of Messrs. William Denny and Bros.' yards at Dumbarton.

Gold-Leaf Electroscope.—Mr. L. Benoist, in a communication to the Paris Academie of Sciences, described a modification of the old-fashioned gold-leaf electroscope, by which he claims its sensibility is increased nearly 50 per cent. for small divergences. The modification consists simply in the use of three leaves instead of two only. But the day of the electroscope is somewhat gone by.

Light Railways.—In a memorandum issued by the Board of Trade, it is notified that any schemes under the Light Railways Act of the present year must be advertised in the local papers in October or April, and submitted to the Light Railway Commissioners and the county authorities in November and May. Any proposals not sufficiently forward to be advertised next month will have to go over until the spring.

Russian Railways.—There is a report that the Russian Ministry of Ways and Communications have resolved to try at once a series of experiments with electric locomotives on the St. Petersburg and Moscow and the St. Petersburg and Warsaw lines, and on the lines running through the Baltic provinces. Possibly the "electric locomotive" is the Heilmann engine, as it is certain that nothing can be done on these railways with electric traction in the usual sense of the term.

Lightning.—During a thunderstorm which passed over Lamberhurst, Kent, last week, the parish church was struck by lightning. The spire is a shingle-roofed one, and was partially stripped of its shingles, which were scattered in all directions, and one of the shores of the bell-frame was split. The walls were also cracked. None of the woodwork was fired. No information is to hand as to what the lightning conductor was doing, but it is to be presumed that no one nowadays would leave a church steeple without one. Evidently if there was one, it was not very efficient.

Steam-Pipe Coverings.—In a series of tests of non-conducting coverings for boilers and steam-pipes, made for an American insurance company by Prof. Chas. L. Norton, of the Massachusetts Institute of Technology, a somewhat novel method was adopted. The covered pipe was filled with oil, which was heated by a wire carrying an electric current. Obviously, when equilibrium is attained the amount of heat radiated from the pipe is equal to the heating effect of the current, which is easily calculated. Prof. Norton's results mainly relate to "mineral wool" and rock wool, both of which he condemns.

Light Units.—Whatever standard they may ultimately be referred to, it is probable that the Geneva photometric units will at least come into such use as is implied by their being included in text-books. Whether people will actually talk of luxes and lumens is quite a different matter. A technical journal, though not an electrical one, has written "luces," which logically implies "lumina"; but that, of course, is absurd. If they ever get used at all, the words will take English plurals, like any other units. A name for the unit of brightness which would have stood a better chance than these others has not been supplied. It is not our place to suggest one.

Metallic Silicides.—By means of the electric furnace Mr. Moissan has produced and investigated the carbides of most of the less easily reducible metals. Some similar work on the production of metallic silicides has been done by Mr. E. Vigoureux. According to the *Comptes-Rendus* of the Académie, it appears that Mr. Vigoureux finds that in general the heavy metals will not form definite compounds with silicon, though they will dissolve it. Neither will aluminium nor the alkali metals. But the metals of the iron group—chromium, manganese, copper, and platinum—appear to form silicides. There are apparently no silicides comparable to the metallic carbides which are attacked by water.

Gas and Oil Explosions.—On Monday in High street, Homerton, a mineral oil lamp was upset. It exploded, set the room on fire, and burned a woman so severely that she died in the Homerton Infirmary shortly afterwards. On Sunday a gas explosion at Haydon-road, Wimbledon, blew out the windows and doors of a house. Three persons in the house were severely injured, but are expected to recover, and two boys who happened to be walking past the house outside were knocked down and badly cut by the windows as they blew out. Lastly, it is stated that a branch of the telegraph school at Reading has been wrecked by a gas explosion, but in this case no personal injuries are reported.

A Wonderful Torpedo.—A torpedo is being secretly constructed at Boston, in America, by a Lieutenant Halpine, but has not escaped the eagle eye of the Dalziel agent. "It is to contain an electric motor of sufficient power to propel it for 22 knots by means of a screw, and also a great length of piano wire, by means of which the operator will control its movements." The operator "may be on shore or in a ship or small boat, or may, in case of necessity, float on the water by means of a life preserver." This last provision seems so entirely unnecessary, unless, indeed, the operator chooses to ride out to sea on the back of his torpedo until he meets an enemy's ship, and then deftly dismount and smash her up.

Very Cheap Illumination.—All sorts of arguments are pressed into service from time to time at town council meetings as reasons for not adopting electric lighting, and the last is the coming of acetylene. At Dudley a councillor informed his colleagues that there was "now a new illuminant called acetylene which was five times more powerful than gas, and could be supplied at 6d. per 1,000ft." Moreover, the plant sufficient to supply a town like Dudley could be laid down for £5,000. Thus a local paper has it, but of course the worthy councillor may have been misheard by the reporter. The council as a whole, however, clearly knew better, because they passed the resolution for the appointment of a committee to consider the electric lighting of the borough.

An Electrical Autolycus.—At the Marylebone Police Court, a young man named Ernest Otter, of Cambridge-road, Hammersmith, has been charged with stealing a miscellaneous collection of articles, including a banjo, field glasses, musical-box, and gold pin, belonging to Mr. D. Cornfoot, a merchant, residing at 20, Lancaster-gate, Hyde Park. The prisoner was employed to fit up Mr. Cornfoot's house with the electric light, and the articles were missed and subsequently found at his rooms. The charge was not denied, but the prisoner was committed for trial. Something has been written and much has been said as to the wickedness of the wireman, but up to the present this has been exhibited in the way of bad work rather than in the felonious collection of portable property.

New Form of Cell.—It might be imagined that every possible way of arranging the zinc, carbon, and pot in a zinc-carbon cell had been tried by this time. However, the *Elektrotechnischer Anzeiger* describes a cell in which the zinc is in the form of a double cylinder with a flat bottom to it. In the annular space between the inner and outer zinc cylinders comes the carbon, which is also of cylindrical form, the three cylinders having the same axis. The annular spaces between the carbon and the zinc are filled with a paste in the usual way, and a store of liquid fills the innermost space. Details may be omitted, and would not in any event be of much use without an illustration, but the above is the principle of the thing. It is the invention of Mr. Paul Schmidt, of Berlin, and has been patented.

Direct Coupling to Gas-Engines.—There are so many exhibitions, large and small, this year that one is in danger of forgetting which is which. There has been one at Stuttgart. It is a local affair, but one noticeable thing in the account of the gas and oil engines exhibited there which is given by *Dinglers Polytechnisches Journal* is the direct-coupled dynamo and gas-engine of Korting Bros., of Hanover. One of these is figured and briefly described. The engine is a tandem cylinder one, with apparently a very moderately heavy flywheel for a gas engine, and the eight-pole dynamo is coupled to the same shaft. There, is, however, what looks like a very heavy strap rigger bolted on to the flywheel—for what purpose is not clear. A single-cylinder gas-engine direct coupled to a six-pole dynamo is also illustrated. Unfortunately, there are no details as to the performance of these machines.

Nuremberg Exhibition.—Brief reference has already been made to the Bavarian exhibition at Nuremberg. Their position on the spot naturally enables the Schuckert Company to make a big show there in the machinery building. They undertake the illumination of the exhibition, and the generating plant is, so to say, part of the show, being erected on a platform at the end of the machinery hall. Both continuous and alternating current systems are used for this, and there are considerably more arc lamps on the alternating-current mains than on the continuous ones. A prominent exhibit is the 300-kilowatt alternator with its field exciter on the same shaft. This machine, together with a high-voltage continuous-current dynamo and a converter, is illustrated and briefly described in the *Elektrotechnischer Anzeiger*. The converter is for producing single, two-phase, and three-phase alternating currents from a continuous current.

Obituary.—During the week the death has been announced of Prof. Luigi Palmieri, the director of the Vesuvius Observatory. Mr. Palmieri was at one time professor of physics in the marine college at Naples, and afterwards in the university. He devoted some considerable attention to terrestrial electricity and magnetism, and, for use in the Vesuvius Observatory, designed two new instruments, one for the study of the variations in the amount and kind of atmospheric electricity, and another an electrical seismograph. Prof. Palmieri was a member of the Italian Senate.—From America comes the news of the death of Prof. W. Shrader, the head of the electrical department at the Missouri University at Columbia in that State.—The death has also been announced of Dr. J. E. C. Munro, who was once a president of the British Association, and was the author of a work on the Patents, Designs, and Trade Mark Acts of 1883.

Cable-Eating Insects.—There have been some curious reports as to the destruction of the insulation of a cable in Tonquin by insects. It was put down to the white ants, but as the cable was lead sheathed, it was very reasonably objected that that had hitherto proved a sufficient protection against them. The French Telegraphic Department sent a portion of the damaged cable to Mr. E. L. Bouvier for examination. He found the insulation had been destroyed by the formation of a quantity of small holes, evidently the work of some insect. On a minute examination the heads of two insects were discovered which were believed to be those of white ants, and it is supposed that they must have got at the insulation either from a bad joint or some accidental hole in the lead covering. Whether the insects are the ordinary white ants or not, it appears certain that they belong to some species of termite. As a remedy it is suggested that the cotton covering should be treated with sulphate of copper.

Electro-Harmonic Society. — The first smoking concert of the season has been fixed by the Electro-Harmonic Society for Friday, September 25, 1896, at the St. James's Hall Restaurant, Regent-street, W., at eight o'clock. The musical directors are, as hitherto, Mr. T. E. Gatehouse and Mr. Alfred E. Izard, and the programme will be as follows—Part I.: glee, "By Celia's Arbour" (Horsley), the "Dilettante" Vocal Quartette; pianoforte solo, "Gavotte" (Sapellnikoff), Mr. Alfred E. Izard; song, "Maid of Athens" (Gounod), Mr. Frederick Bevan; recitation, "Mr. Stack's Story" (Adeler), Mr. W. G. Churcher; song, "Edward Gray" (Sullivan), Mr. Edward Dalzell; silver bells, "The Promise of Life" (Cowen), Mr. R. B. Hopkins; song, "Flow, Thou Regal Purple Stream" (Dr. Arnold), Mr. Robert Hilton; musical sketch, "The Opera" (Schneider), Mr. George Schneider. Part II.: glee, "Simple Simon" (Macy), the "Dilettante" Vocal Quartette; recitation, "McBrae's Plan" (Wood), Mr. W. G. Churcher; new song, "Lass o' mine" (F. Bevan), Mr. Frederick Bevan; silver bells, "Alice" (Ascher), Mr. R. B. Hopkins; song (with refrain), "The Clown's Song" (Hatton), Mr. E. Dalzell; song, "My Lodging is the Cellar here" (Old German), Mr. Robert Hilton; humorous song, "That Awful Joke" (Kent), Mr. George Schneider.

Chemical Society.—In the September issue of the *Journal* of the Chemical Society Messrs. H. B. Dixon and H. Bereton Baker's paper is printed, giving the results of their investigations as to whether Röntgen radiations are able to influence chemical change, either by starting it or by accelerating or diminishing it after it has been started by ordinary light. In all cases negative results were obtained. The substances tried were mixtures of carbon monoxide and oxygen (dried and moist), hydrogen and oxygen, hydrogen and chlorine, carbon monoxide and chlorine, hydrogen sulphide and sulphur dioxide, solutions of sodium sulphite and oxygen, slow oxidation of phosphorus, and the decomposition of hydrogen peroxide. The authors, however, give no countenance to the idea that the action of

Digitized by Google

the rays on a photographic place takes place indirectly through a fluorescence of the glass back. Papers by Dr. A. Richardson and Miss Emily Forbey are on the subject of the formation of hydrogen peroxide in ethyl ether, amyl alcohol, and other organic substances under the influence of sunlight. Three of the "abstracts" relate to matters connected with electrolysis. Mr. Donato Tommasi's rotating cathode has been already described in these columns. From the investigations of Mr. Giacomo Carrara it appears that methyl alcohol used as a solvent exerts a dissociating effect on most electrolytes comparable with that exerted by water, but no constant ratio exists between the solutions of the same substance in water and methyl alcohol; which was to be expected. From another abstract, it seems that the dielectric constant for various mixtures of organic liquids is not calculable by the simple mixture rule. It is generally lower than this, but the reverse when ether is one of the liquids.

Mining Engineers.—The seventh annual general meeting of the Federated Institution of Mining Engineers was opened at Cardiff on Tuesday in the room of the South Wales Institute of Engineers, Park-place. The institution comprises six societies: the Chesterfield and Midland Counties Institution of Engineers, Midland Institute of Mining, Civil, and Mechanical Engineers, Mining Institute of Scotland, North of England Institute of Mining and Mechanical Engineers, North Staffordshire Institute of Mining and Mechanical Engineers, and South Staffordshire and East Worcestershire Institute of Mining Engineers. Mr. G. A. Mitchell, Newcastle, president of the institution, occupied the chair. It was announced that the newly-elected president of the institution was Mr. Lindsay Wood, the well-known engineer and colliery proprietor, of North Durham. The vice-presidents for the year include Sir W. T. Lewis and Sir Lowthian Bell. A paper on anthracite coal was read by Mr. W. D. Wight. He began by stating that while the production of anthracite coal in the United States had rapidly increased, until the output in 1895 reached the enormous total of 58 million tons, South Wales anthracite deposits had been comparatively neglected, and the trade for that quality of coal had languished. This could be explained only by the circumstances that in the past the purposes to which anthracite had been applied were limited. The benefits to the community, especially in great cities, arising from the use of an absolutely smokeless combustible ought not be lost sight of. Mr. Morgan W. Davies (Swansea) said anthracite coal could be burned in almost every variety of grate, and Mr. Hort (Wrexham) said in burning anthracite coal for household purposes they must discard "the old-fashioned notion" of poking the fire. Among the other subjects discussed were papers by Prof. W. Galloway on "Secondary Haulage," and by Mr. W. D. Wight on "Automatic Variable Expansion Gear."

An Electric Subway.—Many years ago it became apparent that Boston required additional facilities for the transportation of street-car passengers through the lower parts of the city. The problem was for a time somewhat solved by the introduction of a very complete system of overhead trolley lines covering the city and immediate suburbs. From the æsthetic and sentimental standpoints, to which the Americans are not always so blind as is generally believed, this wholesale introduction of the overhead wire was not acceptable, and, moreover, as the population increased, the electric roads proved inadequate to deal with the traffic in the congested portions of the city. This applies to the region about Boston Common, where, especially on Tremont-street, bordering its eastern side, blockades are of very frequent occurrence. The result was the formation of a commission to build a subway or subways to take the traffic in the vicinity of the Common, to build a tunnel under Beacon-hill, to build a tunnel in the vicinity of Scolley-square, and to lay out a new way from a point near the south-east corner of the Common to Franklin Park. The commission at once began its work, and the progress made has been described in the *Scientific American*. By surface and sub-surface surveys the exact nature of the ground was determined, and these preliminary investigations included studies with regard to the disposition of underground sewers, pipes, and conduits that might be met with on the line selected. Part of the subway is to be for two tracks and part for four, but the electrical part of the work appears still to be done. The rail-level is to be only about 17ft. below the surface of the ground, and consequently where the subway ran under trees there was trouble. These have, in general, been lifted bodily and left on the same spot. A trench was dug around the tree, and the earth was then undercut so as to form a great earth ball. Chains were passed beneath it and carried to four screwjacks, by means of which it was raised to the new level. "The operation being done in winter," says our contemporary, "enabled the engineers to secure a solid earth ball under the influence of frost, thereby greatly facilitating the work." No doubt that was a convenient way from an engineering point of view. It would be more interesting to know how the trees look at the present moment. Few English trees would survive such treatment.

Cycles and Telegraphs.—According to the *Scientific American*, special attention has been given by the Signal Corps of the United States army to provisions for temporary telegraphic or telephonic intercommunication, and among pending experiments are some relating to the naked wire telephone, a subject which has already been mentioned more than once in these notes. A more curious matter, however, is the use of bicycles for the reeling out and recovering of wire and outpost cable by bicycle, as to which it is said that the results have been very satisfactory, and the United States Army Signal Corps has now a bicycle equipped with an automatic reel that works perfectly. The attachment was made in San Antonio, Texas, under the supervision of its inventor, Captain R. E. Thompson, of the Signal Corps. The line was laid out and recovered at a moderate rate on the day of the first test. The speed was gradually increased, and it was found that the wire was paid out quickly. "After dismounting for a moment to reverse the action, the officer began a return trip, keeping in the middle of the road and riding hard. The recovery was perfectly made, the wire being spooled evenly and the tension was at no time troublesome, although the course of the line was occasionally departed from by many feet, showing that the problem of compensating for increased speed of the recovery due to increasing bulk of the spool has been solved. The time occupied in running out and then picking up the reel of wire was two minutes, the reel holding about one-third of a mile of cable. Practical use has been made of the equipment in sending messages at other times than on the trial trip." Our contemporary gives an illustration, not of the United States Army apparatus, but of a similar one designed by Mr. L. Kamm, a German, who, however, lives in this country. The apparatus for laying the wire weighs 7lb., and each mile of wire weighs 10lb. There has recently, we know, been a good deal done in the way of military cycling at Aldershot, but we must acknowledge as having derived from our American contemporary the news that part of it was the trial of Mr. Kamm's machine there. Except under very special conditions of country or climate, one would imagine that the method could not

Digitized by Google

be of any great value for distances of more than a mile or two, and will probably fail to supersede flag signalling. A cycle even without its trail of wire cuts a poor figure on the rough ground of cross-country work.

Electrolysis of Water.—An abstract of a paper by Mr. Alexei Sokoloff in the *Annalen Physiker Chemie* has been published in the *Journal* of the Chemical Society. It deals with the question of the minimum E.M.F. required to produce electrolysis in water and the difficulties of determining it. According to Helmholtz, the E.M.F. required for the electrolysis of water depends directly on the densities of the hydrogen and oxygen at the electrodes; the smaller these densities, the weaker will be the E.M.F. required; and in a liquid from which all gas has been completely removed, the value must sink to zero. Helmholtz has further deduced an expression connecting the E.M.F. of polarisation, A, for any pressures, p_h and p_o, of the hydrogen and oxygen, with the E.M.F. when the pressure p_a is the atmospheric, and determined the value of this last quantity, A_a, as being 1·783 volts. A direct proof that the decomposition of water can be accomplished with any E.M.F., however small, has not yet been given, nor can Helmholtz's determination of A_a be regarded as final; the author has therefore submitted these points to further experimental investigation. In order to obtain proof of electrolysis when the E.M.F. is very small, a voltameter was arranged, which contained two platinum plates as electrodes, and in the immediate neighbourhood of each plate an insulated platinum point. When a current is passed, the electrodes become polarised by gas layers of definite density, but as these gases are electrically neutral, and therefore quite free, they diffuse through the liquid, and must in a short time reach the platinum points and polarise these just as each electrode was originally polarised. This polarisation can then be easily detected by means of a sensitive electrometer. The experiments quoted in the paper in which this arrangement was employed show that electrolysis can be produced by any E.M.F. however small. In contradiction to Helmholtz, the author finds that an E.M.F. of one volt suffices to produce gas of measurable pressure by the decomposition of water. Thus, in one experiment, which lasted 16 months, a calomel cell (1·072 volt) produced gas of 2·53mm. pressure, and from the continual increase in the pressure this seems to be even far below the limiting value. From the results it appears that difficulties are encountered in producing invisible electrolysis with a small E.M.F. similar to those met with when visible electrolysis is effected. Forces are active on the surfaces of the electrodes which restrain the gases from freely diffusing through the liquid, and bring about absorption of the gases by platinum and other metals. The forces here spoken of introduce difficulties in the determination of A_a from the results of experiments on visible electrolysis. Determinations which the author has made at low pressures give a value for A_a of 0·745 volt, which is much smaller than that given by Helmholtz.

Photometric Standards.—As we have already noted, about the only definite resolution arrived at at the electrical congress at Geneva was the recommendation of the Violle standard of light for adoption, by which all secondary standards are to be referred to the light emitted by one square centimetre of melted platinum at the point of solidification. This may or may not be adopted as a theoretical standard in France and elsewhere, but it is so expensive to set up (a relatively considerable quantity of platinum has to be melted), and such precautions must be observed, that it is altogether impossible as a practical standard. The Germans, it is pretty certain, will continue to use the Hefner lamp, which, by the resolutions of the congress, they are permitted to do "provisionally." Prof. E. Hospitalier, who presided over the discussion, however, says that this only means that they will call a "hefner" what the French call a "decimal candle," which is the practical unit. This depends on circumstances. The melting point of platinum cannot be altered, but, of course, it is always possible to adopt Prof. Mengarini's suggestion and alter the lamp if it does not turn out to be, as the "decimal" candle is, an accurate twentieth of the standard. The propriety of using such unhandy substances as melting platinum or incandescing carbon appears to have been taken all through as beyond discussion, and, indeed, Mr. Von Hefner Alteneck was asked at Geneva what his lamp was supposed to represent the equivalent of. That it might represent itself did not appear to be considered possible by any of the supporters of the Violle standard. Yet apart from questions of convenience, it does not seem clear why a given area of burning amyl acetate should be essentially improper as a standard in comparison with a specified area of melting platinum. Indeed, there seems no small amount of pedantry in the matter. A more practical question is the relation of the new standard, the "decimal candle," to the English candle. Different observers have determined the Hefner standard at various figures between ·88 and ·98 of the English candle, but as, on the best authority, the latter standard with the most careful use must be expected to vary 3·5 per cent., is very likely to vary as much as 8 per cent. and may vary 15 per cent., it is clear that any figures beyond the first decimal place are of a purely ornamental character, and it is therefore difficult to say much more than that the new candle would be a "little less" than the old one. A more serious objection is that the colour of the amyl acetate flame is distinctly redder than any of the lights in ordinary use. In a communication published in the *Transactions* of the American Institute of Electrical Engineers, Prof. R. A. Fessenden has emphasised this point. He says that two eyes may differ by 50 per cent. in their estimate of the relative brightness of a coloured light referred to a monochromatic one, and that with the various lights from white to yellow in ordinary use it would be impossible to get a greater accuracy than ½ per cent. from this cause alone. One of the few advantages of using an acetylene flame as a standard would be its white colour, as was pointed out in America by Mr. Steinmetz. But, after all, it does not very much matter, for the practical use of a unit of light is to enable one to say a given lamp is of so many candle-power—and that must always be a very rough matter.

Rontgen Radiations.—To-day (Friday), if the programme is carried out, the British Association is to discuss Prof. Röntgen's discovery at length. The subject has already been referred to in the presidential address, chiefly, of course, from the physiological side. Sir Joseph Lister is not altogether disinclined to lend countenance to the suggestion that the transmission of the radiations "through the human body may not be altogether a matter of indifference to the internal organs." This can hardly, however, be the case with such radiations, as the viscera are absolutely transparent to; for if the radiations pass through without losing any energy, they can obviously have done no work in their passage. But at the same time as the Röntgen radiations proper there are always generated a quantity of ordinary light, and no doubt also a very considerable amount of ultra-violet radiations, using that term in the ordinary sense. The latter are known to be extraordinarily effective in producing sunburn, and the skin irritation which has been

Digitized by Google

observed to follow the long-continued action of the Röntgen apparatus on the human body may very probably be referred to constituents more nearly approaching radiations of this character than the true Röntgen ray. Such radiations would not penetrate deeply, and doubtless, if necessary, could be stopped by a suitable screen. When the subject is discussed at Liverpool it is to be hoped that mere descriptions of unconnected results will not be allowed to postpone an adequate treatment of the theory of the subject by those competent to deal with the question. The reluctance of the high authorities on the theory of light to say anything definite on the subject has been hitherto somewhat unaccountable. Some time ago Sir George Stokes took the occasion of a meeting of the Victoria Institute to pronounce in favour of the hypothesis of transverse vibrations of very small wave-length, but by the time his address came to be published he appeared to have changed his mind in favour of an explanation which should be not "periodic in character." What that may mean is not clear, unless it is something corpuscular. Some good mathematics and a great deal of bad speculation has been wasted on the subject, but the matter may be put quite shortly. Apart from an altogether new hypothesis, the only theory that gets over even elementary difficulties is that the Röntgen radiations are simply exceedingly short (invisible) light waves. Theoretical considerations show that such waves, as soon as they become of a size not much greater or smaller than the molecules or atoms, would act very much as the Röntgen rays do. The only difficulty is the mechanical one of conceiving how the atom is capable of giving vibrations of so high a frequency. But we know really nothing of the mechanics of the atom, so this is no objection. Moreover, there is another conception which is just possible. The original vibrations may not be those of the atom or molecule, but of portions of the luminiferous medium contained in the interstices of the molecule or atom. In that case the wave-lengths would be some simple fraction of the molecular or atomic dimensions—which is just what is wanted. The analogy of a metal tube containing air is immediately apparent in the case of sound-waves. The same result follows on the favourite, though, as it appears to the writer at present, unwarranted, theory of an atom with an "atmosphere" of "ether" sticking round it. And on the electromagnetic theory of light the violent projection of the highly "charged" molecules from the cathode on to the anode or the glass of the tube, seems about as likely a way of getting up this sort of vibration as any other. Anyone who works it out will see that this gives a possible explanation of many of the conditions necessary to get good radiation when the cathode rays are projected on the surface of the tube instead of on the anode. We do not, however, intend to attempt that here.

Scientific Education.—Prof. T. E. Thorpe, who has already expressed views on the subject elsewhere, cut into the *Times* correspondence on the way to make a chemical expert at the end of last week. He does not wish "to minimise the value of classical learning, or to underrate the services that Oxford, for example, has rendered to scholarship and literature," but "if the universities did more for science, the schools which they influence would follow suit, and a sounder public opinion concerning the part which science should play in education, and of the relation of science to industry, would more quickly grow." It is to be feared that if we have to wait for Oxford to produce him, the chemical researcher will not be very common yet awhile. A sort of mild socialism is more in the way of the advanced party on the Isis than anything scientific. Prof. Thorpe says the examination system is in fault. Of course it is; you can only examine in things that are known. If the honour went to the man that made the discovery instead of the man that topped the class list, it might be different. Mr. Friswell returns to the charge. His contention is that it is all the fault of the manufacturer. The German schools are open to the whole world, and large numbers of Englishmen and Americans study at them, but even when educated abroad Englishmen do not meet the chemical manufacturers' requirements. Though individual exceptions exist, the English manufacturer does not value science as he ought. The reason of this is the want of appreciation of the value of science which our ordinary system of education leaves in the minds of the public at large. Sir B. Samuelson, instead of complaining because the classical schoolmaster stands by his own trade, goes straight for the other people who wasted the money that might have been usefully applied "In 1889-91, thanks to Mr. Acland and Mr. Goschen, the 'beer money' was allowed to be applied to technical education, and because people had heard of great polytechnical schools on the Continent they set to work and established so-called 'polytechnics' on the model of the Polytechnic in Regent-street." The artisans of the Continent have, as a rule, no scientific instruction whatever, but in the great colour works of Germany doctors of philosophy direct every department. "To expect that we should vanquish our rival manufacturers by teaching chemistry or physics to our artisans is as if we were to prepare our army to conquer the enemy by instructing 'Tommy Atkins' in strategy and tactics." Lastly, Sir B. Samuelson praises general cultivation and a liberal rather than a scientific education. Theoretically, this is right, since a wide and general knowledge enables a man to quickly pick up and deal with new ideas and processes. Unfortunately, the advocate of a general education is a Janus-like being, who really means a specialisation in a portion of the literatures of an extinct civilisation. There is usually no great difficulty in getting round to the other face and making him dilate on the futility of "a mere smattering of science and modern languages." Sir B. Samuelson's letter called forth a reply from a correspondent who signs himself "Y," but who is evidently someone of authority, as the *Times* treats him to larger type than any of the others. Briefly, he thinks that it can do no harm for a workman to have a few right notions about his work instead of a great many wrong ones. "At the present time what career is open, except that of a teacher, to a thoroughly instructed chemist or physicist as such? What salary may he reasonably expect to get unless he has capital or 'business capacity'?" The conclusion is again, as before, that the first steps must be to clear away ignorance and apathy, and no longer to allow "the old universities to dominate all education and bribe all the rising talent into one narrow groove of intellectual training." Mr. J. E. Marsh comes up again with a suggestion that there should be an enquiry. That is futile, if you put the people responsible for the present system on the commission; they will not condemn themselves. If you do not, the enquiry will not be "impartial." Lastly, a Mr. W. Smith puts forward the curious view that the German boy works instead of plays at school because when he leaves it he has to go into the army and be bullied in a despicable way by the non-commissioned officer. The facts may be true, but there seems no logical connection between them. The reason why the English grammar school goes in for games and, having failed to teach classics, teaches cricket and football, is simply because it is the easiest and most popular thing to do. It would be no use flying from classics, which are hard, to science, which is harder.

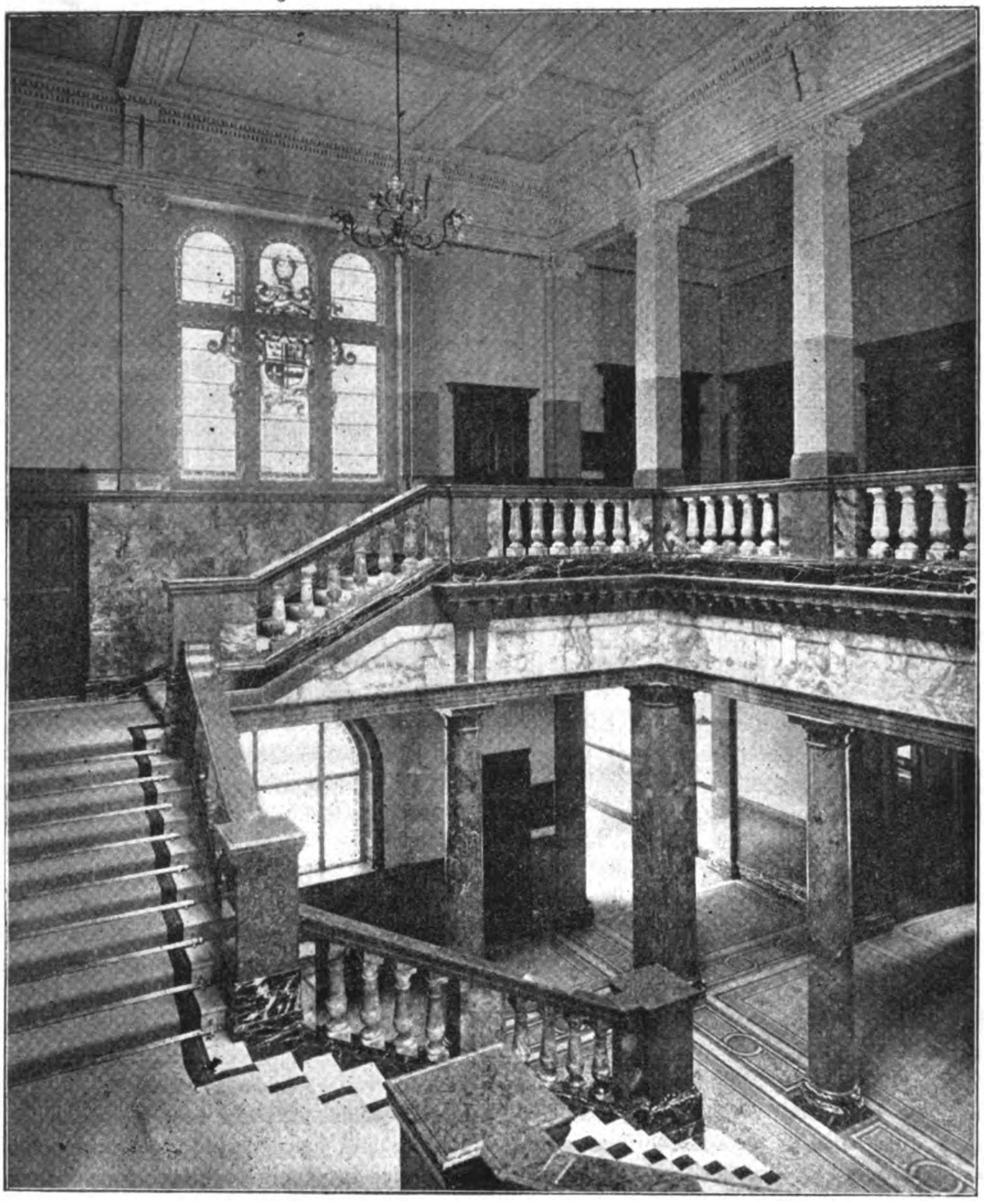
THE ELECTRIC LIGHTING OF THE CROYDON MUNICIPAL BUILDINGS.

This magnificent block of buildings at Croydon, recently opened by the Prince of Wales, contains accommodation for more than the ordinary municipal offices. Thus Mr. Charles Henman, A.R.I.B.A., the architect, in designing the work (now completed) provided for a public library, reading-rooms, and a corn exchange, in addition to the court-rooms, Council-chamber, and offices required for the municipal work. The architecture of the handsome block has been previously described in the public Press, and we need not do more than congratulate the Corporation and the architect on the outcome of their labours. The specification for the electric lighting was drawn out by an expert, under the superintendence of Mr. Henman, who has throughout sought to harmonise the fittings with the architecture. About 25 tenders were received, and it was decided to accept that of Messrs. Wenham and Waters, of Paragon Works, Croydon, whose price was £1,253. This selection was made in October last year, after a part of the decorative work had been begun. Still, the firm in question tackled the problem of wiring the building with promptitude, and have now practically finished the work. When the specifications were issued the pressure of supply was stated to be 100 volts, but this has been raised to 200 by the supply company. The sections of the wires and the sub-division of the circuits are thus most ample. We understand that the quality of the work was such that Prof. Kennedy did not hesitate in recommending the Corporation to accept supply at the higher voltage. The only alteration he advised, to make matters quite safe, was the replacing of the smaller switches which did not give sufficient length of break.

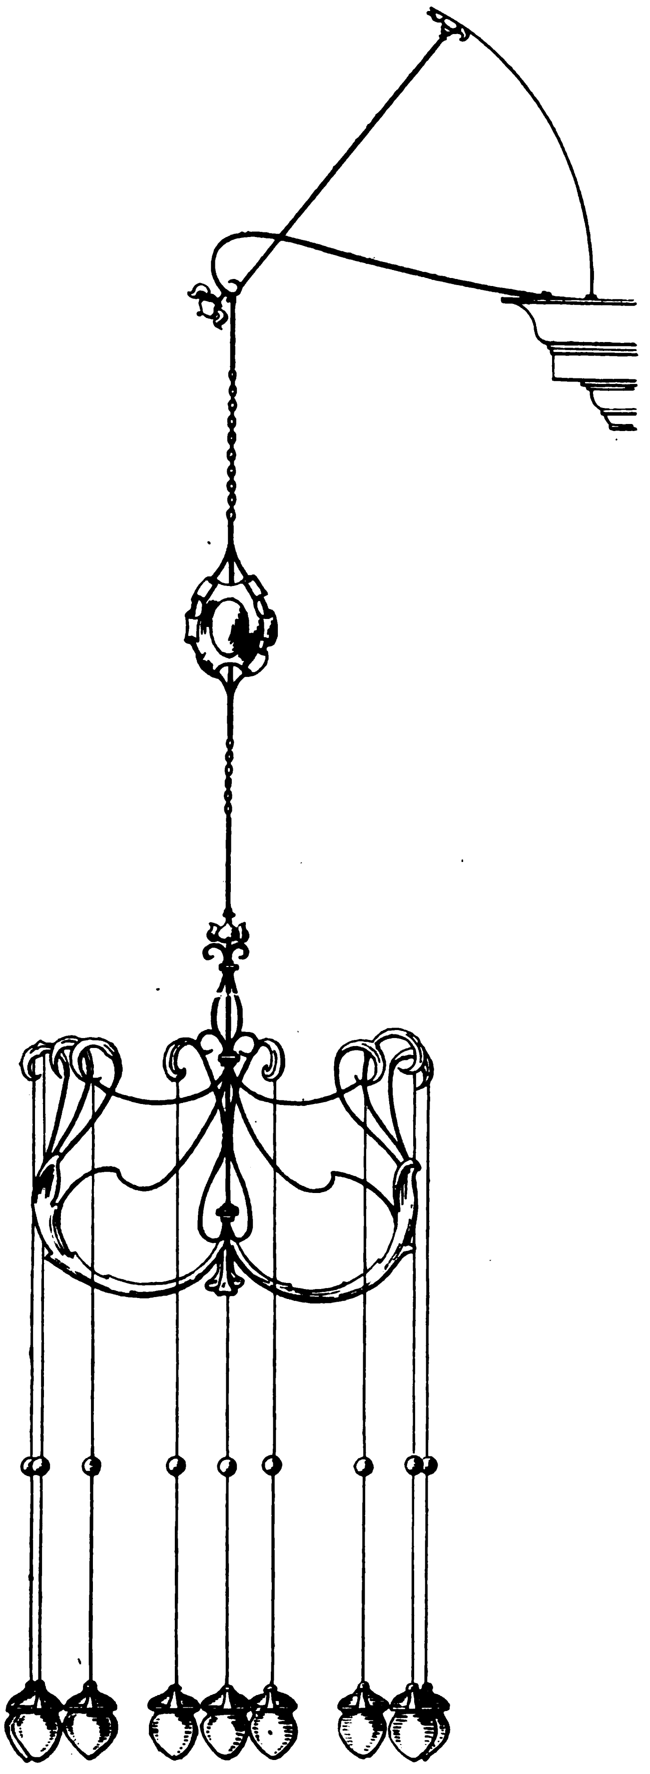
The supply from the street is led into a room in the basement of the buildings by a Callender concentric cable, which terminates in a Reid fuse-box. From this two single cables are led to the main switchboard. The lights controlled by this are equivalent to about 1,000 16-c.p. lamps, and are divided into two main circuits, each controlled by a large double-pole switch. One circuit supplies the municipal offices, Council-chamber, and the courts of justice, while the public library, the Braithwaite Hall, and the corn exchange are lighted by the other circuit. On a panel over the first one containing these two main switches is another with five double-pole distributing switches and fuses, which still further divides the main current. From these the cables, which are all of the Silvertown K type, as specified by the architect, are led throughout the building. The ventilating shafts and trunk mains have been greatly used for carrying the wires. The system of ventilating the building is roughly as follows: Each corridor is of some 3ft. lower pitch than the rooms adjoining it, and the space so formed



The Grand Staircase in the Municipal Buildings, Croydon.

Digitized by Google

between the ceiling of one corridor and the floor of the next is used as an exhaust-air trunk. These trunks are connected by ventilating gratings to each room, and the hot or vitiated atmosphere so collected is taken through the



Sketch of the Fittings used in the Braithwaite Hall.

trunk to a main upcast flue. The centre of this flue is occupied by the boiler flue, and the heat from it assists the upward draught. The mains coming up the upcast are taken out from each floor, and are sub-divided first on a double-pole fuse-board to circuits of under 25 amperes—*i.e.*, 50 amperes on the 100-volt supply. From these the wires are led to further distributing fuse and switch boards at which a further sub-division to five-ampere circuits was intended. As, however, the voltage has been raised to 200 volts, no circuit leaving these boards will carry more than 2½ amperes. In these final circuits there is never any reduction of gauge of wire—a strand of seven 21½ gauge wires is the size which has been almost universally adopted. No fuses have been used in the fittings or in the ceiling roses of pendants, and hence nearly every fuse in the building is grouped and convenient of access. In the air-trunks, and in most of the offices, the wires are laid in wood casing, but where glazed brickwork has to be crossed in the corridors the wires are encased in iron pipes. In other places steel tubes are used embedded in the plaster, and suitable draw-boxes are then provided.

The fittings generally throughout the offices and corridors are of a simple type. The usual plain pendant with opal shade is strongly in evidence, and in most places harmonises well with the surroundings. In the office a few pendants to light the rooms generally are supplemented by simple brackets in the walls over the various desks. In several of the offices plugs are provided for portable lamps. In the two courts the lighting is effected by pendants dropping from the sides of the rectangular skylight. In the larger court the effect is most pleasing, but we did not care for it in the small building, where the individual lights come rather too close together. The highly insulated cords are then too prominent, and give a streaky appearance in daylight. When the lamps are alight this may not, however, be noticed. On the second floor are the committee-rooms, forming a range of three, with folding-doors between them. The first of these rooms will be used on occasions as a reception-room, and from it opens out the mayor's retiring-room. The fittings in this range are of graceful design, finished with a steel bronze, which is most pleasing. They are mostly for five lights each, but a few two-light wall brackets of the same general type are also used. It is in the Council-chamber that the most striking effects are found. The fittings here are designed on bold lines and executed in hammered iron and copper work. The lamps are hung from the fittings by flexible cords, as can be seen in the illustration of a similar fitting used in the Braithwaite Hall. In the Council-chamber are six long pendants, with fancy shade to each fitting, and one central lamp with larger shade. The general effect of these from the floor is exceedingly good. The designs for these fittings, and for those in the Braithwaite Hall, were drawn by Mr. F. E. Tomlinson from suggestions by and to the approval of Mr. Henman, and were manufactured by the Waltham Engineering Company in their Westminster works. The fittings used in the grand staircase can also be seen from the illustration. The attendant's rooms are in the tower and are approached by a spiral staircase. The lamps on this are wired to two tramway switches—one placed at the top and one at the bottom of the staircase. The connections are such that the lamps can be switched on or off from either switch, which is of great service. Thus, if the attendant is rung up after dark he can light the whole of the stairs simultaneously before he descends. The clock at top of the tower is also provided with electric light for illuminating the four dials. Ten lamps are used to each of the dials, which are 10ft. diameter. These are attached to a frame of ordinary electric light moulding, forming a circle about equal in diameter to that of the figures of the dial. These lamps are provided with enamelled iron reflectors, and are automatically switched on by a gear fixed to the clock, which gear has been designed by Messrs. Wenham and Waters. The public library adjoins the municipal building, and can be entered from it when desired by the officials. In the lending library simple pendants are used, arranged in lines between the book-racks. In the newsroom two-light pendants have been provided, and a most brilliant illumination is the result. The fittings in the reading-room, called the Braithwaite Hall, where the periodicals and the *Electrical Engineer* can be consulted, are illustrated above. The hall has been lighted several times this week, and general satisfaction has been expressed with the effect.

THE BRITISH ASSOCIATION.

LIVERPOOL MEETING.

This year's meeting opened, as is usual, on Wednesday evening with the presidential address in the Philharmonic Hall. A large and brilliant assembly gathered together in this fine hall, when

Sir DOUGLAS GALTON, the retiring president, introduced his successor, and mentioned that personally he was not only retiring from the presidential chair—which high office signalled his retiring from the position of honorary secretary which he had so long held—but also severing a quarter of a century's official connection with the association. He then introduced his eminent successor to the chair.

Sir JOSEPH LISTER, Bart., D.C.L., LL.D., President Royal Society, then read his presidential address.

Presidential Address by Sir Joseph Lister, Bart., D C.L., LL.D., P.R.S.*

My Lord Mayor, my lords, ladies, and gentlemen,—I have first to express my deep sense of gratitude for the great honour conferred upon me by my election to the high office which I occupy to-day. It came upon me as a great surprise. The engrossing claims of surgery have prevented me for many years from attending the meetings of the association, which excludes from her sections medicine in all its branches. This severance of the art of healing from the work of the association was right, and, indeed, inevitable. Not that medicine has little in common with science. The surgeon never performs an operation without the aid of anatomy and physiology; and in what is often the most difficult part of his duty, the selection of the right course to follow, he, like the physician, is guided by pathology, the science of the nature of disease, which, though very difficult from the complexity of its subject-matter, has made during the last half-century astonishing progress; so that the practice of medicine in every department is becoming more and more based on science as distinguished from empiricism. I propose on the present occasion to bring before you some illustrations of the interdependence of science and the healing art; and the first that I will take is perhaps the most astonishing of all results of purely physical enquiry—the discovery of the Röntgen rays, so called after the man who first clearly revealed them to the world. Mysterious as they still are, there is one of their properties which we can all appreciate—their power of passing through substances opaque to ordinary light. There seems to be no relation whatever between transparency in the common sense of the term and penetrability to these emanations. The glasses of a pair of spectacles may arrest them while their wooden and leathern case allows them to pass almost unchecked. Yet they produce, whether directly or indirectly, the same effects as light upon a photographic plate. As a general rule the denser any object is the greater obstacle does it oppose to the rays. Hence, as bone is denser than flesh, if the hand or other part of the body is placed above the sensitive film enclosed in a case of wood or other light material at a suitable distance from the source of the rays, while they pass with the utmost facility through the uncovered parts of the lid of the box and powerfully affect the plate beneath, they are arrested to a large extent by the bones, so that the plate is little acted upon in the parts opposite to them, while the portions corresponding to the muscles and other soft parts are influenced in an intermediate degree. Thus a picture is obtained in which the bones stand out in sharp relief among the flesh, and anything abnormal in their shape or position is clearly displayed.

I need hardly point out what important aid this must give to the surgeon. As an instance, I may mention a case which occurred in the practice of Mr. Howard Marsh. He was called to see a severe injury of the elbow, in which the swelling was so great as to make it impossible for him by ordinary means of examination to decide whether he had to deal with a fracture or a dislocation. If it were the latter, a cure would be effected by the exercise of violence which would be not only useless but most injurious if a bone was broken. By the aid of the Röntgen rays a photograph was taken in which the bone of the upper arm was clearly seen displaced forwards on those of the fore-arm. The diagnosis being thus established, Mr. Marsh proceeded to reduce the dislocation; and his success was proved by another photograph which showed the bones in their natural relative position.

The common metals, such as lead, iron, and copper, being still denser than the osseous structures, these rays can show a bullet embedded in a bone, or a needle lodged about a joint. At the last conversazione of the Royal Society a picture produced by the new photography displayed with perfect distinctness through the bony framework of the chest a halfpenny low down in a boy's gullet. It had been there for six months, causing uneasiness at the pit of the stomach during swallowing, but whether the coin really remained impacted, or, if so, what was its position, was entirely uncertain till the Röntgen rays revealed it. Dr. Macintyre, of Glasgow, who was the photographer, informs me that when the presence of the halfpenny had been thus demonstrated the surgeon in charge of the case made an attempt to extract it, and although this was not successful in its immediate object, it had the effect of dislodging the coin, for a subsequent photograph by Dr. Macintyre not only showed that it had disappeared from the gullet, but also, thanks to the wonderful penetrating power which the rays had acquired in his hands, proved that it had not lodged further down in the alimentary passage. The boy has since completely recovered.

The Röntgen rays cause certain chemical compounds to fluoresce, and emit a faint light plainly visible in the dark; and if they are made to fall upon a translucent screen impregnated with such a salt, it becomes beautifully illuminated. If a part of the human body is interposed between the screen and the source of the rays, the bones and other structures are thrown in shadow upon it, and thus a diagnosis can be made without the delay involved in taking a photograph. It was in fact in this way that Dr. Macintyre first detected the coin in the boy's gullet. Mr. Herbert Jackson, of King's College, London, early distinguished himself in this branch of the subject. There is no reason to suppose that the limits of the capabilities of the rays in this way have yet been reached. By virtue of the greater density of the heart than the adjacent lungs with their contained air, the form and dimensions of that organ in the living body may be displayed on the fluorescent screen, and even its movements have been lately seen by several different observers.

Such important applications of the new rays to medical practice have strongly attracted the interest of the public to them, and I venture to think that they have even served to stimulate the investigations of physicists. The eminent Professor of Physics in the University College of this city (Prof. Lodge) was one of the first to make such practical applications, and I was able to show to the Royal Society at a very early period a photograph, which he had the kindness to send me, of a bullet embedded in the hand. His interest in the medical aspect of the subject remains unabated, and at the same time he has been one of the most distinguished investigators of its purely physical side.

There is another way in which the Röntgen rays connect themselves with physiology, and may possibly influence medicine. It is found that if the skin is long exposed to their action it becomes very much irritated, affected with a sort of aggravated sun burning. This suggests the idea that the transmission of the rays through the human body may be not altogether a matter of indifference to internal organs, but may, by long-continued action produce, according to the condition of the part concerned, injurious irritation or salutary stimulation.

This is the jubilee of anæsthesia in surgery. That priceless blessing to mankind came from America. It had, indeed, been foreshadowed in the first year of this century by Sir Humphry Davy, who, having found a toothache from which he was suffering relieved as he inhaled laughing gas (nitrous oxide), threw out the suggestion that it might perhaps be used for preventing pain in surgical operations. But it was not till on September 30, 1846, Dr. W. T. G. Morton, of Boston, after a series of experiments upon himself and the lower animals, extracted a tooth painlessly from a patient whom he had caused to inhale the vapour of sulphuric ether, that the idea was fully realised. He soon afterwards publicly exhibited his method at the Massachusetts General Hospital, and after that event the great discovery spread rapidly over the civilised world. I witnessed the first operation in England under ether. It was performed by Robert Liston in University College Hospital, and it was a complete success. Soon afterwards I saw the same great surgeon amputate the thigh as painlessly, with less complicated anæsthetic apparatus, by aid of another agent, chloroform, which was being powerfully advocated as a substitute for ether by Dr. (afterwards Sir James Y.) Simpson, who also had the great merit of showing that confinements could be conducted painlessly, yet safely, under its influence. These two agents still hold the field as general anæsthetics for protracted operations, although the gas originally suggested by Davy, in consequence of its rapid action and other advantages, has taken their place in short operations, such as tooth extraction. In the birthplace of anæsthesia ether has always maintained its ground, but in Europe it was to a large extent displaced by chloroform till recently, when many have returned to ether, under the idea that though less convenient, it is safer. For my own part, I believe that chloroform, if carefully administered on right principles, is, on the average, the safer agent of the two.

The discovery of anæsthesia inaugurated a new era in surgery. Not only was the pain of operations abolished, but the serious and sometimes mortal shock which they occasioned to the system was averted, while the patient was saved the terrible ordeal of

* We have condensed this most interesting address, as some of the subjects are hardly within our province.—ED. *E. E.*

Digitized by Google

preparing to endure them. At the same time the field of surgery became widely extended, since many procedures in themselves desirable, but before impossible from the protracted agony they would occasion, became matters of routine practice. Nor have I by any means exhausted the list of the benefits conferred by this discovery.

My next illustration may be taken from the work of Pasteur on fermentations. It was natural that Pasteur should desire to know how the microbes which he showed to be the essential causes of the various fermentations took their origin. It was at that period a prevalent notion, even among many eminent naturalists, that such humble and minute beings originated *de novo* in decomposing organic substances; the doctrine of spontaneous generation, which had been chased successively from various positions which it once occupied among creatures visible to the naked eye, having taken its last refuge where the objects of study were of such minuteness that their habits and history were correspondingly difficult to trace. Here again Pasteur at once saw, as if by instinct, on which side the truth lay; and, perceiving its immense importance, he threw himself with ardour into its demonstration. I may describe briefly one class of experiments which he performed with this object. He charged a series of narrow-necked glass flasks with a decoction of yeast, a liquid peculiarly liable to alteration on exposure to the air. Having boiled the liquid in each flash to kill any living germs it might contain, he sealed its neck with a blow-pipe during ebullition, after which, the flask being allowed to cool, the steam within it condensed, leaving a vacuum above the liquid. If, then, the neck of the flask were broken in any locality, the air at that particular place would rush in to fill the vacuum, carrying with it any living microbes that might be floating in it. The neck of the flask having been again sealed, any germs so introduced would in due time manifest their presence by developing in the clear liquid. When any of such a series of flasks were opened and resealed in an inhabited room or under the trees of a forest, multitudes of minute living forms made their appearance in them, but if this was done in a cellar long unused, where the suspended organisms, like other dust, might be expected to have all fallen to the ground, the decoction remained perfectly clear and unaltered. The oxygen and other gaseous constituents of the atmosphere were thus shown to be of themselves incapable of inducing any organic development in yeast-water.

Such is a sample of the many well-devised experiments by which he carried to most minds the conviction that, as he expressed it, "*la génération spontanée est une chimère*," and that the humblest and minutest living organisms can only originate by parentage from beings like themselves.

Pasteur's labours on fermentation have had a very important influence upon surgery. I have been often asked to speak on my share in this matter before a public audience; but I have hitherto refused to do so, partly because the details are so entirely technical, but chiefly because I have felt an invincible repugnance to what might seem to savour of self-advertisement. The latter objection now no longer exists, since advancing years have indicated that it is right for me to leave to younger men the practice of my dearly loved profession. And it will perhaps be expected that, if I can make myself intelligible, I should say something upon the subject on the present occasion.

Nothing was formerly more striking in surgical experience than the difference in the behaviour of injuries according to whether the skin was implicated or not. Thus, if the bones of the leg were broken and the skin remained intact, the surgeon applied the necessary apparatus without any other anxiety than that of maintaining a good position of the fragments, although the internal injury to bones and soft parts might be very severe. If, on the other hand, a wound of the skin was present communicating with the broken bones, although the damage might be in other respects comparatively slight, the compound fracture, as it was termed, was one of the most dangerous accidents that could happen. Mr. Syme, who was, I believe, the safest surgeon of his time, once told me that he was inclined to think that it would be, on the whole, better if all compound fractures of the leg were subjected to amputation, without any attempt to save the leg. What was the cause of this astonishing difference? It was clearly in some way due to the exposure of the injured parts to the external world. One obvious effect of such exposure was indicated by the odour of the discharge, which showed that the blood in the wound had undergone putrefactive change, by which the bland nutrient liquid had been converted into highly irritating and poisonous substances. I have seen a man with compound fracture of the leg die within two days of the accident, as plainly poisoned by the products of putrefaction as if he had taken a fatal dose of some potent toxic drug.

An external wound of the soft parts might be healed in one of two ways. If its surfaces were clean cut and could be brought into accurate apposition, it might unite rapidly and painlessly "by the first intention." This, however, was exceptional. Too often the surgeon's efforts to obtain primary union were frustrated: the wound inflamed, and the retentive stitches had to be removed, allowing it to gape; and then, as if it had been left open from the first, healing had to be effected in the other way—*i.e.*, that of granulation and cicatrisation—a process which, when it proceeded unchecked to its completion, commanded our profound admiration. It was, however, essentially tedious compared with primary union, while, as we have seen, it was always preceded by more or less inflammation and fever, sometimes very serious in their effects. It was also liable to unforeseen interruptions.

It will be readily understood from the above description that the inflammation which so often frustrated the surgeon's endeavours after primary union was, in my opinion, essentially due to decomposition of blood within the wound.

These and many other considerations had long impressed me with the greatness of the evil of putrefaction in surgery. I had done my best to mitigate it by scrupulous ordinary cleanliness and the use of various deodorant lotions. But to prevent it altogether appeared hopeless while we believed with Liebig that its primary cause was the atmospheric oxygen which, in accordance with the researches of Graham, could not fail to be perpetually diffused through the porous dressings which were used to absorb the blood discharged from the wound. But when Pasteur had shown that putrefaction was a fermentation caused by the growth of microbes, and that these could not arise *de novo* in the decomposable substance, the problem assumed a more hopeful aspect. If the wound could be treated with some substance which, without doing too serious mischief to the human tissues, would kill the microbes already contained in it and prevent the future access of others in the living state, putrefaction might be prevented, however freely the air with its oxygen might enter. I had heard of carbolic acid as having a remarkable deodorising effect upon sewage, and having obtained from my colleague, Dr. Anderson, Professor of Chemistry in the University of Glasgow, a sample which he had of this product, then little more than a chemical curiosity in Scotland, I determined to try it in compound fractures. Applying it undiluted to the wound, with an arrangement for its occasional renewal, I had the joy of seeing these formidable injuries follow the same safe and tranquil course as simple fractures, in which the skin remains unbroken.

The appliances which I first used for carrying out the antiseptic principle were both rude and needlessly complicated. The years that have since passed have witnessed great improvements in both respects. Of the various materials which have been employed by myself and others, and their modes of application, I need say nothing except to express my belief, as a matter of long experience, that carbolic acid, by virtue of its powerful affinity for the epidermis and oily matters associated with it, and also its great penetrating power, is still the best agent at our disposal for purifying the skin around the wound.

Even our earlier and ruder methods of carrying out the antiseptic principle soon produced a wonderful change in my surgical wards in the Glasgow Royal Infirmary, which, from being some of the most unhealthy in the kingdom, became, as I believe I may say without exaggeration, the healthiest in the world, while other wards, separated from mine only by a passage a few feet broad, where former modes of treatment were for a while continued, retained their former insalubrity.

The striking results of the application of the germ theory to surgery acted as a powerful stimulus to the investigation of the nature of the micro-organisms concerned, and it soon appeared that putrefaction was by no means the only evil of microbic origin to which wounds were liable, and I ventured to express the view that, just as the various fermentations had each its special microbe, so it might be with the various complications of wounds. This surmise was afterwards amply verified.

Not that we can look forward with anything like confidence to being able ever to see the *materies morbi* of every disease of this nature. One of the latest of such discoveries has been that by Pfeiffer, of Berlin, of the bacillus of influenza, perhaps the most minute of all micro-organisms ever yet detected. The bacillus of anthrax, the cause of a plague common among cattle in some parts of Europe, and often communicated to sorters of foreign wool in this country, is a giant as compared with this tiny being; and supposing the microbe of any infectious fever to be as much smaller than the influenza bacillus as this is less than that of anthrax, a by no means unlikely hypothesis, it is probable that it would never be visible to man. The improvements of the microscope, based on the principle established by my father in the earlier part of the century, have apparently nearly reached the limits of what is possible. But that such parasites are really the causes of all this great class of diseases can no longer be doubted.

The first rational step towards the prevention or cure of disease is to know its cause; and it is impossible to overestimate the practical value of researches such as those to which I am now referring. Among their many achievements is what may be fairly regarded as the most important discovery ever made in pathology, because it revealed the true nature of the disease which causes more sickness and death in the human race than any other. It was made by Robert Koch, who at the London congress in 1881 showed to us for the first time the bacillus of tubercle. Wonderful light was thrown by this

Digitized by Google

discovery upon a great group of diseases which had before been rather guessed than known to be of an allied nature; a precision and efficacy never before possible was introduced into their surgical treatment, while the physician became guided by new and sure light as regards their diagnosis and prevention.

At the same London congress Koch demonstrated to us his "plate culture" of bacteria, which is so important that it was soon introduced into his own institute and other laboratories throughout the world, and it has immensely facilitated bacteriological study. One fruit of it in Koch's own hands was the discovery of the microbe of cholera in India, whither he went to study the disease.

I have next to invite your attention to some earlier work of Pasteur. There is a disease known in France under the name of *choléra des poules*, which often produced great havoc among the poultry yards of Paris. It had been observed that the blood of birds that had died of this disease was peopled by a multitude of minute bacteria, not very dissimilar in form and size to the microbe of the lactic ferment to which I have before referred. And Pasteur found that, if this bacterium was cultivated outside the body for a protracted period under certain conditions, it underwent a remarkable diminution of its virulence; so that, if inoculated into a healthy fowl, it no longer caused the death of the bird, as it would have done in its original condition, but produced a milder form of the disease which was not fatal. And this altered character of the microbe, caused by certain conditions, was found to persist in successive generations cultivated in the ordinary way. Thus was discovered the great fact of what Pasteur termed the *atténuation des virus*, which at once gave the clue to understanding what had before been quite mysterious, the difference in virulence of the same disease in different epidemics.

But he made the further very important observation that a bird which had gone through the mild form of the complaint had acquired immunity against it in its most virulent condition. Pasteur afterwards succeeded in obtaining mitigated varieties of microbes for some other diseases, and he applied with great success the principle which he had discovered. The preparations used for such preventive inoculations he termed "vaccins" in honour of our great countryman, Edward Jenner. For Pasteur at once saw the analogy between the immunity to fowl-cholera produced by its attenuated virus and the protection afforded against small-pox by vaccination.

In 1880 Pasteur entered upon the study of that terrible but then most obscure disease, hydrophobia or rabies, which from its infective character he was sure must be of microbic origin, although no micro-organism could be detected in it. He early demonstrated the new pathological fact that the virus had its essential seat in the nervous system. This proved the key to his success in this subject.

It was shown several years ago by Roux and Yersin, working in the Institut Pasteur, that the crust or false membrane which forms upon the throats of patients affected with diphtheria contains bacteria which can be cultivated outside the body in a nutrient liquid, with the result that it acquires poisonous qualities of astonishing intensity, comparable to that of the secretion of the poison gland of the most venomous serpents. And they also ascertained that the liquid retained this property after the microbes had been removed from it by filtration, which proved that the poison must be a chemical substance in solution, as distinguished from the living element which had produced it. These poisonous products of bacteria, or toxins, as they have been termed, explain the deadly effects of some microbes, which it would otherwise be impossible to understand. Thus, in diphtheria itself the special bacillus does not become propagated in the blood, but remains confined to the surface on which it first appeared, but the toxin which it secretes is absorbed from that surface into the blood, and so poisons the system. Similar observations have been made with regard to the microbes of some other diseases, as, for example, the bacillus of tetanus or lockjaw. This remains localised in the wound, but forms a special toxin of extreme potency, which becomes absorbed and diffused through the body.

Wonderful as it seems, each poisonous microbe appears to form its own peculiar toxin. Koch's tuberculin was of this nature, a product of the growth of the tubercle bacillus in culture media. Here, again, great effects were produced by extremely minute quantities of the substance. Results led Koch to believe that he had obtained an effectual means of dealing with tubercular disease in all its forms. Unhappily, the apparent cure proved to be only of transient duration, and the high hopes which had been inspired by Koch's great reputation were dashed. It is but fair to say that he was strongly urged to publish before he was himself disposed to do so, and we cannot but regret that he yielded to the pressure put upon him.

Still, valuable results sprang from Koch's work on tuberculin, which has also indirectly done good in other ways. His distinguished pupil, Behring, has expressly attributed to those researches the inspiration of the work which led him and his since famous collaborateur, the Japanese Kitasato, to their surprising discovery of anti-toxic serum. They found that if an animal of a species liable to diphtheria or tetanus received a quantity of the respective toxin, so small as to be harmless, and afterwards, at suitable intervals, successively stronger and stronger doses, the creature, in course of time, acquired such a tolerance for the poison as to be able to receive with impunity a quantity very much greater than would at the outset have proved fatal. So far, we have nothing more than seems to correspond with the effects of the increasingly potent cords in Pasteur's treatment of rabies. But what was entirely new in their results was that if blood was drawn from an animal which had acquired this high degree of artificial immunity, and some of the clear fluid or serum which exuded from it after it had clotted was introduced under the skin of another animal, this second animal acquired a strong, though more transient, immunity against the particular toxin concerned. The serum in some way counteracted the toxin, or was antitoxic. But, more than that, if some of the antitoxic serum was applied to an animal after it had already received a poisonous dose of the toxin, it preserved the life of the creature, provided that too long a time had not elapsed after the poison was introduced. In other words, the antitoxin proved to be not only preventive but curative.

Similar results were afterwards obtained by Ehrlich, of Berlin, with some poisons not of bacterial origin but derived from the vegetable kingdom, and quite recently the independent labours of Calmette, of Lille and Fraser, of Edinburgh, have shown that antidotes of wonderful efficacy against the venom of serpents may be procured on the same principle.

Behring's darling object was to discover means of curing tetanus and diphtheria in man. In tetanus the conditions are not favourable because the specific bacilli lurk in the depths of the wound and only declare their presence by symptoms caused by their toxin having been already in a greater or less amount diffused through the system, and in every case of this disease there must be a fear that the antidote may be applied too late to be useful; but in diphtheria the bacilli very early manifest their presence by the false membrane which they cause upon the throat, so that the antitoxin has a fair chance, and here we are justified in saying that Behring's object has been attained.

I might have taken equally striking illustrations of my theme from other departments in which microbes play no part; in fact, any attempt to speak of all that the art of healing has borrowed from science and contributed to it during the past half-century would involve a very extensive dissertation on pathology and therapeutics. I have culled specimens from a wide field, and I only hope that in bringing them before you I have not overstepped the bounds of what is fitting before a mixed company. For many of you my remarks can have had little, if any, novelty; for others they may, perhaps, possess some interest as showing that medicine is no unworthy ally of the British Association—that, while her practice is ever more and more based on science, the ceaseless efforts of her votaries to improve what have been fittingly designated *Quæ prosunt omnibus artes*, are ever adding largely to the sum of abstract knowledge.

Address to the Mathematical and Physical Section.

BY PROF. J. J. THOMSON, M.A., F.R.S., PRESIDENT OF THE SECTION.

There is a melancholy reminiscence connected with this meeting of our section, for when the British Association last met in Liverpool the chair in Section A was occupied by Clerk-Maxwell. In the quarter of a century which has elapsed since that meeting, one of the most important advances made in our science has been the researches which, inspired by Maxwell's view of electrical action, confirmed that view and revolutionised our conception of the processes occurring in the electromagnetic field. When the association last met in Liverpool Maxwell's view was almost without supporters; to-day its opponents are fewer than its supporters then. Maxwell's theory, which is the development and extension of Faraday's, has not only affected our way of regarding the older phenomena of electricity—it has, in the hands of Hertz and others, led to the discovery of whole regions of phenomena previously undreamt of. It is sad to think that his premature death prevented him from reaping the harvest he had sown. His writings are, however, with us, and are a storehouse to which we continually turn, and never, I think, without finding something valuable and suggestive.

"Thus ye teach us day by day
Wisdom, though now far away."

The past year has been rich in matters of interest to physicists. In it has occurred the jubilee of Lord Kelvin's tenure of the professorship of natural philosophy at the University of Glasgow. Some of us were privileged to see this year at Glasgow an event unprecedented in the history of physical science in England, when congratulations to Lord Kelvin on the jubilee of his professorship were offered by people of every condition and country. Every scientific society and every

Digitized by Google

scientific man is Lord Kelvin's debtor; but no society and no body of men owe him a greater debt than Section A of the British Association. He has done more for this section than anyone else; he has rarely missed its meetings; he has contributed to the section papers which will make its proceedings imperishable, and by his enthusiasm he has year by year inspired the workers in this section to renew with increased vigour their struggles to penetrate the secrets of nature. Long may we continue to receive from him the encouragement and assistance which have been so freely given for the past half-century.

By the death of Sir W. R. Grove, the inventor of Grove's cell, we have lost a physicist whose name is a familiar one in every laboratory in the world. Besides the Grove cell, we owe to him the discovery of the gas battery, and a series of researches on the electrical behaviour of gases, whose importance is only now beginning to be appreciated. His essay on the correlation of the physical forces had great influence in promoting that belief in the unity of the various branches of physics which is one of the characteristic features of modern natural philosophy.

In the late Prof. Stoletow, of Moscow, we have lost the author of a series of most interesting researches on the electrical properties of gases illuminated by ultra-violet light, researches which from their place of publication are, I am afraid, not so well known in this country as they deserve to be.

As one who unfortunately of late years has had only too many opportunities of judging of the teaching of science in our public and secondary schools, I should like to bear testimony to the great improvement which has taken place in the teaching of physics in these schools during the past 10 years. The standard attained in physics by the pupils of these schools is increasing year by year, and great credit is due to those by whose labours this improvement has been accomplished. I hope I may not be considered ungrateful if I express the opinion that in the zeal and energy which is now spent in the teaching of physics in schools there may lurk a temptation to make the pupils cover too much ground. You may by careful organisation and arrangement ensure that boys shall be taken over many branches of physics in the course of a short time; it is, indeed, not uncommon to find boys of 17 or 18 who have compassed almost the whole range of physical subjects. But, although you may increase the rate at which information is acquired, you cannot increase in anything like the same proportion the rate at which the subject is assimilated so as to become a means of strengthening the mind and a permanent mental endowment when the facts have long been forgotten.

Physics can be taught so as to be a subject of the greatest possible educational value; but when it is so, it is not so much because the student acquires a knowledge of a number of interesting and important facts as by the mental training the study affords in, as Maxwell said, "bringing our theoretical knowledge to bear on the objects and the objects on our theoretical knowledge." I think this training can be got better by going very slowly through such a subject as mechanics, making the students try innumerable experiments of the simplest and, what is a matter of importance in school teaching, of the most inexpensive kind, but always endeavouring to arrive at numerical results rather than by attempting to cover the whole range of mechanics, light, heat, sound, electricity, and magnetism. I confess I regret the presence in examinations intended for school boys of many of these subjects.

I think, too, that in the teaching of physics at our universities there is perhaps a tendency to make the course too complex and too complete. I refer especially to the training of those students who intend to become physicists. I think that after a student has been trained to take accurate observations, to be alive to those pitfalls and errors to which all experiments are liable, mischief may in some cases be done if, with the view of learning a knowledge of methods, he is kept performing elaborate experiments, the results of which are well known. It is not given to many to wear a load of learning lightly as a flower. With many students a load of learning, especially if it takes a long time to acquire, is apt to crush enthusiasm. Now, there is, I think, hardly any quality more essential to success in physical investigations than enthusiasm. Any investigation in experimental physics requires a large expenditure of both time and patience; the apparatus seldom, if ever, begins by behaving as it ought; there are times when all the forces of nature, all the properties of matter, seem to be fighting against us; the instruments behave in the most capricious way, and we appreciate Coutts Trotter's saying that the doctrine of the constancy of nature could never have been discovered in a laboratory. These difficulties have to be overcome, but it may take weeks or months to do so, and unless the student is enthusiastic he is apt to retire disheartened from the contest. I think, therefore, that the preservation of youthful enthusiasm is one of the most important points for consideration in the training of physicists. In my opinion this can best be done by allowing the student, even before he is supposed to be acquainted with the whole of physics, to begin some original research of a simple kind under the guidance of a teacher who will encourage him and assist in the removal of difficulties. If the student once tastes the delights of the successful completion of an investigation he is not likely to go back, and will be better equipped for investigating the secrets of nature than if, like the White Knight of "Alice in Wonderland," he commences his career knowing how to measure or weigh every physical quantity under the sun, but with little desire or enthusiasm to have anything to do with any of them. Even for those students who intend to devote themselves to other pursuits than physical investigation, the benefits derived from original investigation as a means of general education can hardly be over-estimated, the necessity it entails of independent thought, perseverance in overcoming difficulties, and the weighing of evidence gives it an educational value which can hardly be rivalled. We have to congratulate ourselves that through the munificence of Mr. Ludwig Mond in providing and endowing a laboratory for research, the opportunities for pursuing original investigations in this country have been greatly increased.

The discovery at the end of last year by Prof. Röntgen of a new kind of radiation from a highly exhausted tube through which an electric discharge is passing, has aroused an amount of interest unprecedented in the history of physical science. The effects produced inside such a tube by the cathode rays, the bright phosphorescence of the glass, the shadows thrown by opaque objects, the deflection of the rays by a magnet, have, thanks to the researches of Crookes and Goldstein, long been familiar to us, but it is only recently that the remarkable effects which occur outside such a tube have been discovered. In 1893, Lenard, using a tube provided with a window made of a very thin plate of aluminium, found that a screen impregnated with a solution of a phosphorescent substance became luminous if placed outside the tube in the prolongation of the line from the cathode through the aluminium window. He also found that photographic plates placed outside the tube in this line were affected, and electrified bodies were discharged: he also obtained by these rays photographs through plates of aluminium or quartz. He found that the rays were affected by a magnet, and regarded them as the prolongations of the cathode rays. This discovery was at the end of last year followed by that of Röntgen, who found that the region round the discharge tube is traversed by rays which affect a photographic plate after passing through substances such as aluminium or cardboard, which are opaque to ordinary light; which pass from one substance to another, without any refraction, and with but little regular reflection; and which are not affected by a magnet. We may, I think, for the purposes of discussion, conveniently divide the rays occurring in or near a vacuum tube traversed by an electric current into three classes, without thereby implying that they are necessarily distinctly different in physical character. We have (1) the cathode rays inside the tube, which are deflected by a magnet; (2) the Lenard rays outside the tube, which are also deflected by a magnet; and (3) the Röntgen rays, which are not, as far as is known, deflected by a magnet. Two views are held as to the nature of the cathode rays—one view is that they are particles of gas carrying charges of negative electricity and moving with great velocities which they have acquired as they travelled through the intense electric field which exists in the neighbourhood of the negative electrode. The phosphorescence of the glass is on this view produced by the impact of these rapidly moving charged particles, though whether it is produced by the mechanical violence of the impact or whether it is due to an electromagnetic impulse produced by the sudden reversal of the velocity of the negatively-charged particle—whether, in fact, it is due to mechanical or electrical causes, is an open question. This view of the constitution of the cathode rays explains in a simple way the deflection of those rays in a magnetic field, and it has lately received strong confirmation from the results of an experiment made by Perrin. Perrin placed inside the exhausted tube a cylindrical metal vessel with a small hole in it, and connected this cylinder with the leaves of a gold-leaf electroscope. The cathode rays could, by means of a magnet, be guided so as either to pass into the cylinder through the aperture, or turned quite away from it. Perrin found that when the cathode rays passed into the cylinder the gold leaf of the electroscope diverged, and had a negative charge, showing that the bundle of cathode rays enclosed by the cylinder had a charge of negative electricity. Crookes had many years ago exposed a disc connected with a gold-leaf electroscope to the bombardment of the cathode rays, and found that the disc received a slight positive charge; with this arrangement, however, the charged particles had to give up their charges to the disc if the gold leaves of the electroscope were to be affected, and we know that it is extremely difficult, if not impossible, to get electricity out of a charged gas merely by bringing the gas in contact with a metal. Lord Kelvin's electric strainers are an example of this. It is a feature of Perrin's experiment that since it acts by induction the indications of the electroscope are independent of the communication of the charges of electricity from the gas to the cylinder, and since the cathode rays fall on the inside of the cylinder, the electroscope would not be affected, even if there were such an effect as is produced when ultra-violet light falls upon the

Digitized by Google

surface of an electro-negative metal when the metal acquires a positive charge. Since any such process cannot affect the total amount of electricity inside the cylinder, it will not affect the gold leaves of the electroscope ; in fact, Perrin's experiments proved that the cathode rays carry a charge of negative electricity.

The other view held as to the constitution of the cathode rays is that they are waves in the ether. It would seem difficult to account for the result of Perrin's experiment on this view, and also I think very difficult to account for the magnetic deflection of the rays. Let us take the case of a uniform magnetic field. The experiments which have been made on the magnetic deflection of these rays seem to make it clear that in a magnetic field which is sensibly uniform, the path of these rays is curved. Now, if these rays were due to ether waves, the curvature of the path would show that the velocity of propagation of these waves varied from point to point of the path. That is, the velocity of propagation of these waves is not only affected by the magnetic field, it is affected differently at different parts of the field. But in a uniform field what is there to differentiate one part from another, so as to account for the variability of the velocity of wave propagation in such a field? The curvature of the path in a uniform field could not be accounted for by supposing that the velocity of this wave motion depended on the strength of the magnetic field, or that the magnetic field, by distorting the shape of the boundary of the negative dark space, changed the direction of the wave front, and so produced a deflection of the rays. The chief reason for supposing that the cathode rays are a species of wave motion is afforded by Lenard's discovery, that when the cathode rays in a vacuum tube fall on a thin aluminium window in the tube, rays having similar properties are observed on the side of the window outside the tube ; this is readily explained on the hypothesis that the rays are a species of wave motion to which the window is partially transparent, while it is not very likely that particles of the gas in the tube could force their way through a piece of metal. This discovery of Lenard's does, not, however, seem to me incompatible with the view that the cathode rays are due to negatively charged particles moving with high velocities. The space outside Lenard's tube must have been traversed by Röntgen rays ; these would put the surrounding gas in a state in which a current would be readily started in the gas if any E.M.F. acted upon it. Now, though the metal window in Lenard's experiments was connected with the earth and would, therefore, screen off from the outside of the tube any effect arising from slow electrostatic changes in the tube, it does not follow that it would be able to screen off the electrostatic effect of charged particles moving to and from the tube with very great rapidity. For in order to screen off electrostatic effects there must be a definite distribution of electrification over the screen ; changes in this distribution, however, take a finite time, which depends upon the dimensions of the screen and the electrical conductivity of the material of which it is made. If the electrical changes in the tube take place at above a certain rate, the distribution of electricity on the screen will not have time to adjust itself, and the screen will cease to shield off all electrostatic effects. Thus the very rapid electrical changes which would take place if rapidly moving charged bodies were striking against the window might give rise to E.M.F.'s in the region outside the window, and produce convection currents in the gas which has been made a conductor by the Röntgen rays. The Lenard rays would thus be analogous in character to the cathode rays, both being convective currents of electricity. Though there are some points in the behaviour of these Lenard rays which do not admit of a very ready explanation from this point of view, yet the difficulties in its way seem to me considerably less than that of supposing that a wave in the ether can change its velocity when moving from point to point in a uniform magnetic field.

I now pass on to the consideration of the Röntgen rays. We are not yet acquainted with any crucial experiment which shows unmistakably that these rays are waves of transverse vibration in the ether, or that they are waves of normal vibration, or, indeed, that they are vibrations at all. As a working hypothesis, however, it may be worth while considering the question whether there is any property known to be possessed by these rays which is not possessed by some form or other of light. The many forms of light have in the last few months received a noteworthy addition by the discovery of M. Becquerel of an invisible radiation, possessing many of the properties of the Röntgen rays, which is emitted by many fluorescent subtances, and to an especially marked extent by the uranium salts. By means of this radiation, which, since it can be polarised, is unquestionably light, photographs through opaque substances similar to, though not so beautiful as, those obtained by means of Röntgen rays, can be taken, and, like the Röntgen rays, they cause an electrified body on which they shine to lose its charge, whether this be positive or negative.

The two respects in which the Röntgen rays differ from light is in the absence of refraction, and perhaps of polarisation. Let us consider the absence of refraction first. We know cases in which special rays of the spectrum pass from one substance to another without refraction—for example, Kundt showed that gold, silver, copper allow some rays to pass through them without bending, while other rays are bent in the wrong direction. Pflüger has lately found that the same is true for some of the aniline dyes when in a solid form. In addition to this, the theory of dispersion of light shows that there will be no bending when the frequency of the vibration is very great. I have here a curve taken from a paper by Helmholtz, which shows the relation between the refractive index and the frequency of vibration for a substance whose molecules have a natural period of vibration, and one only ; the frequency of this vibration is represented by O K in the diagram. The refractive index increases with the frequency of the light until the latter is equal to the frequency of the natural vibration of the substance ; the refractive index then diminishes, becomes less than unity, and finally approaches unity, and is practically equal to it when the frequency of the light greatly exceeds that of the natural vibration of the molecule. Helmholtz's results are obtained on the supposition that a molecule of the refracting substance consists of a pair of oppositely electrified atoms, and that the specific inductive capacity of the medium consists of two parts—one due to the ether, the other to the setting of the molecules along the lines of electric force.

Starting from this supposition, we can easily see without mathematical analysis that the relation between the refractive index and the frequency must be of the kind indicated by the curve. Let us suppose that an E.M.F. of given amplitude acts on this mixture of molecules and ether, and let us start with the frequency of the external E.M.F. less than that of the free vibrations of the molecules. As the period of the force approaches that of the molecules the effect of the force in pulling the molecules into line will increase. Thus the specific inductive capacity, and therefore the refractive index, increases with the frequency of the external force. The effect of the force on the orientation of the molecules will be greatest when the period of the force coincides with that of the molecules. As long as the frequency of the force is less than that of the molecules, the external field tends to make the molecules set so as to increase the specific inductive capacity of the mixture. As soon, however, as the frequency of the force exceeds that of the molecules, the molecules, if there are no viscous forces, will all topple over and point so as to make the part of the specific inductive capacity due to the molecules of opposite sign to that due to the ether. Thus, for frequencies greater than that of the molecules the specific inductive capacity will be less than unity. When the frequency of the force only slightly exceeds that of the molecules, the effect of the external field on the molecules is very great, so that if there are a considerable number of molecules, the negative part of the specific inductive capacity due to the molecules may be greater than the positive part due to the ether, so that the specific inductive capacity of the mixture of molecules and ether would be negative; no waves of this period could then travel through the medium: they would be totally reflected from the surface.

As the frequency of the force gets greater and greater, its effect in making the molecules set will get less and less, but the waves will continue to be totally reflected until the negative part of the specific inductive capacity due to the molecules is just equal to the positive part due to the ether. Here the refractive index of the mixture is zero. As the frequency of the force increases, its effect on the molecules gets less and less, so that the specific inductive capacity continually approaches that due to the ether alone, and practically coincides with it as soon as the frequency of the force is a considerable multiple of that of the molecules. In this case both the specific inductive capacity and the refractive index of the medium are the same as that of the ether, and there is consequently no refraction. Thus, the absence of refraction, instead of being in contradiction to the Röntgen rays, being a kind of light, is exactly what we should expect if the wave-length of the light were exceedingly small.

The other objection to these rays being a kind of light is that there is no very conclusive evidence of the existence of polarisation. Numerous experiments have been made on the difference between the absorption of these rays by a pair of tourmaline plates when their axes are crossed or parallel. Many observers have failed to observe any difference at all between the absorption in the two cases. Prince Galitzine and M. de Karnojitsky, by a kind of cumulative method, have obtained photographs which seem to show that there is a slightly greater absorption when the axes are crossed than there is when the axes are parallel. There can, however, be no question that the effect, if it exists at all, is exceedingly small compared with the corresponding effect for visible light. Analogy, however, leads us to expect that to get polarisation effects we must use in the case of short waves polarisers of a much finer structure than would be necessary for long ones. Thus a wire bird-cage will polarise long electrical waves, but will have no effect on visible light. Rubens and Du Bois made an instrument which would polarise the infra-red rays by winding very fine wires very close together on a framework ; this arrangement, however, was too coarse to polarise visible light. Thus, though the structure of the tour

Digitized by Google

maline is fine enough to polarise the visible rays, it may be much too coarse to polarise the Röntgen rays if these have exceedingly small wave-lengths. As far as our knowledge of these rays extends, I think we may say that though there is no direct evidence that they are a kind of light, there are no properties of the rays which are not possessed by some variety of light.

It is clear that if the Röntgen rays are light rays their wave-lengths are of an entirely different order to those of visible light. It is, perhaps, worth notice that on the electromagnetic theory of light we might expect two different types of vibration if we suppose that the atoms in the molecule of the vibrating substance carried electrical charges. One set of vibrations would be due to the oscillations of the bodies carrying the charges, the other set to the oscillation of the charges on these bodies. The wave-length of the second set of vibrations would be commensurate with molecular dimensions. Can these vibrations be the Röntgen rays? If so, we should expect them to be damped with such rapidity as to resemble electrical impulses rather than sustained vibrations.

If we turn from the rays themselves to the effects they produce, we find that the rays alter the properties of the substances through which they are passing. This change is most apparent in the effects produced on the electrical properties of the substances. A gas, for example, while transmitting these rays is a conductor of electricity. It retains its conducting properties for some little time after the rays have ceased to pass through it, but Mr. Rutherford and I have lately found that the conductivity is destroyed if a current of electricity is sent through the Röntgenised gas. The gas in this state behaves in this respect like a very dilute solution of an electrolyte. Such a solution would cease to conduct after enough electricity had been sent through it to electrolyse all the molecules of the electrolyte. When a current is passing through a gas exposed to the rays, the current destroys and the rays produce the structure which gives conductivity to the gas; when things have reached a steady state the rate of destruction by the current must equal the rate of production by the rays. The current can thus not exceed a definite value, otherwise more of the conducting gas would be destroyed than is produced.

This explains the very characteristic feature that in the passage of electricity through gases exposed to Röntgen rays, the current, though at first proportional to the E.M.F., soon reaches a value where it is almost constant and independent of the E.M.F., and we get to a state when a tenfold increase in the E.M.F. only increases the current by a few per cent. The conductivity under the Röntgen rays varies greatly from one gas to another; the halogens and their gaseous compounds, the compounds of sulphur, and mercury vapour are among the best conductors. It is worthy of note that those gases which are the best conductors when exposed to the rays are either elements, or compounds of elements, which have in comparison with their valency very high refractive indices.

The conductivity conferred by the rays on a gas is not destroyed by a considerable rise in temperature; it is, for example, not destroyed if it be sucked through metal tubing raised to a red heat. The conductivity is, however, destroyed if the gas is made to bubble through water; it is also destroyed if the gas is forced through a plug of glass wool. This last effect seems to indicate that the structure which confers conductivity on the gas is of a very coarse kind, and we get confirmation of this from the fact that a very thin layer of gas exposed to the Röntgen rays does not conduct nearly so well as a thicker one. I think we have evidence from other sources that electrical conduction is a process that requires a considerable space—a space large enough to enclose a very large number of molecules.

Thus Koller found that the specific resistance of petroleum, turpentine, and distilled water, when determined from experiments made with very thin layers of these substances, was very much larger than when determined from experiments with thicker layers. Even in the case of metals there is evidence that the metal has to be of appreciable size if it is to conduct electricity. The theory of the scattering of light by small particles shows that, if we assume the truth of the electromagnetic theory of light, the effects should be different according as the small particles are insulators or conductors. When the small particles are non-conductors, theory and experiment concur in showing that the direction of complete polarisation for the scattered light is at right angles to the direction of the incident light, while if the small particles are conductors, theory indicates that the direction of complete polarisation makes an angle of 60deg. with the incident light. This result is not, however, confirmed by the experiments made by Prof. Threlfall on the scattering of light by very small particles of gold. He found that the gold scattered the light in just the same way as a non-conductor, giving complete polarisation at right angles to the incident light. This would seem to indicate that those very finely divided metallic particles no longer acted as conductors. Thus there seems evidence that in the case of conduction through gases, through badly conducting liquids and through metals, electric conduction is a process which requires a very considerable space and aggregations of large numbers of molecules. I have not been able to find any direct experimental evidence as to whether the same is true for electrolytes. Experiments on the resistance of thin layers of electrolytes would be of considerable interest, as, according to one widely accepted view of electrolysis conduction through electrolytes, so far from being effected by aggregations of molecules, takes place by means of the ion, a structure simpler than that of the molecule, so that if this represents the process of electrolytic conduction, there would not seem room for the occurrence of an effect which occurs with every other kind of conduction.

In this building it is only fitting that some reference should be made to the question of the movement of the ether. You are all doubtless acquainted with the heroic attempts made by Prof. Lodge to set the ether in motion, and how successfully the ether resisted them. It seems to be conclusively proved that a solid body in motion does not set in motion the ether at an appreciable distance outside it; so that if the ether is disturbed at all in such a case, the disturbance is not comparable with that produced by a solid moving through an incompressible fluid, but must be more analogous to that which would be produced by the motion through the liquid of a body of very open structure, such as a piece of wire netting, where the motion of the fluid only extends to a distance comparable with the diameter of the wire, and not with that of the piece of netting. There is another class of phenomena relating to the movement of the ether which is, I think, deserving of consideration, and that is the effect of a varying electromagnetic field in setting the ether in motion. I do not remember to have seen it pointed out that the electromagnetic theory of light implicitly assumes that the ether is not set in motion even when acted on by mechanical forces. On the electromagnetic theory of light such forces do exist, and the equations used are only applicable when the ether is at rest. Consider, for example, the case of a plane electric wave travelling through the ether. We have parallel to the wave front a varying electric polarisation, which on the theory is equivalent to a current; at right angles to this, and also in the wave front, we have a magnetic force. Now, when a current flows through a medium in a magnetic field there is a force acting on the medium at right angles to the plane, which is parallel both to the current and to the magnetic force; there will thus be a mechanical force acting on each unit volume of the ether when transmitting an electric wave, and since this force is at right angles to the current and to the magnetic force, it will be in the direction in which the wave is propagated. In the electromagnetic theory of light, however, we assume that this force does not set the ether in motion, as unless we made this assumption we should have to modify our equations, as the electromagnetic equations are not the same in a moving field as in a field at rest. In fact, a complete discussion of the transmission of electromagnetic disturbances requires a knowledge of the constitution of the ether which we do not possess. We now assume that the ether is not set in motion by an electromagnetic wave. If we do not make this assumption we must introduce into our equation quantities representing the components of the velocity of the ether, and unless we know the constitution of the ether, so as to be able to deduce these velocities from the forces acting on it, there will be in the equations of the electromagnetic field more unknown quantities than we have equations to determine. It is, therefore, a very essential point in electromagnetic theory to investigate whether or not there is any motion of the ether in a varying electromagnetic field. We have at the Cavendish Laboratory, using Prof. Lodge's arrangement of interference fringes, made some experiments to see if we could detect any movement of the ether in the neighbourhood of an electric vibrator, using the spark which starts the vibrations as the source of light. The movement of the ether, if it exists, will be oscillatory, and with an undamped vibrator the average velocity would be zero; we used, therefore, a heavily damped vibrator, with which the average velocity might be expected to be finite. The experiments are not complete, but so far the results are entirely negative. We also tried by the same method to see if we could detect any movement of the ether in the neighbourhood of a vacuum tube emitting Röntgen rays, but could not find any trace of such a movement. Prof. Threlfall, who independently tried the same experiment has, I believe, arrived at the same conclusion.

Unless the ether is immovable under the mechanical forces in a varying electromagnetic field, there are a multitude of phenomena awaiting discovery. If the ether does move, then the velocity of transmission of electrical vibrations, and therefore of light, will be affected by a steady magnetic field. Such a field, even if containing nothing but ether, will behave towards light like a crystal, and the velocity of propagation will depend upon the direction of the rays. A similar result would also hold in a steady electric field. We may hope that experiments on these and similar points may throw some light on the properties of that medium which is universal, which plays so large a part in our explanation of physical phenomena, and of which we know so little.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE B. A. AT LIVERPOOL.

The British Association meeting at Liverpool is in full swing. It is surprising how rapidly in this age of scientific progress new subjects of surpassing interest claim the attention of the various sections. Our readers are more interested in the physical and mechanical sections than in the others, but it must not be forgotten that when the physicists or the engineers fail to provide an exciting topic, the chemists, biologists, geographers, or economists may have their turn. This year, however, it is the turn of the physicists. The air is full of Röntgen rays. The phenomena are discussed in the sectional meetings, but perhaps more is said and opinions are more freely expressed when a group of physicists meet in social converse. Most men of repute prefer to theorise in private rather than to commit themselves in public till experimental proofs accumulate, all pointing towards one theory. It is not often, however, that a discovery of so recondite a character can be immediately utilised for the benefit of mankind. Röntgen, however, has provided the medical profession with a weapon of the greatest service, and surgeons were not slow in adopting its aid. As the president of the association remarks, Prof. O. Lodge, at Liverpool, was among the first to aid the medical men of that town in using the new discovery. Since then the exact seats of certain forms of disease of the bony structure of the body have been made clear, and no doubt as time rolls on, the use of the Röntgen ray photographic apparatus will be common to every surgeon. Naturally we look to the president of Section A to put his imprimatur upon the most probable theory to explain the new discovery; but Prof. J. J. Thomson is cautious, and while clearing the ground of many false surmises, and pointing out that these rays have properties which some form or other of light possess, he does not go so far as to say they are a form of light. We think, however, a careful investigation of this sectional president's address will show that the inwardly expressed view is that Röntgen's discovery is the discovery of a new form of light, with shorter wave-lengths and greater velocity than the forms hitherto investigated. We are glad to find so carefully expressed the view that the past failure to obtain polarisation of the Röntgen rays may be due rather to the apparatus than to the non-polarisability of the rays. Two other topics of great interest are to be found in this address. It is somewhat reassuring to hear from so eminent a professor that the standard of physical education is rising, as well as to receive the hint of danger in attempting too much. The facility to answer examination questions upon a variety of subjects is no proof of real education; and we have always feared that the craze to accept the position of a man in an examination as a proof of ability has been of late years a little over-ridden. We agree with Prof. Thomson that a thorough grounding, with the retention of youthful enthusiasm, is more likely to benefit the man and the world than the attempt to fill him up with knowledge upon every conceivable topic. Crichtons are rare. The other question to which we have referred is that relating to the ether. When

Digitized by Google

the British Association last met at Liverpool the chair of Section A was occupied by Clerk-Maxwell. He consolidated, so to speak, the modern views respecting the ether and electricity, and even now many are only beginning to realise the depth of his insight into these branches of physics. Prof. J. J. Thomson refers to the efforts of Prof. O. Lodge to obtain motion of ether by the motion of ponderable matter, and his failure. The failure, he points out, is in accord with the late Prof. J. Clerk-Maxwell's mathematical investigations, and that if the equation there given is correct, no motion of the ether can ensue upon the motion of matter.

We shall remark upon but one other sectional address—that of Sir Douglas Fox to Section G. The president of Section G is, we think, hardly correct in his conclusions concerning electrical enterprise in England, and this arises from a mistaken comparison between what has been done in the States and what has been done here. Here we had systems of lighting and traction in full swing before the era of the electrical engineers. America had nothing of the kind, or to a very limited extent. The field to be worked there was a blank—here it was fully occupied. It is a very different thing to have to get rid of the old, before introducing the new, to the having no old to get rid of. America, in the natural order of things, was compelled to get ahead on the new lines. Much harm has been done, and will be done, from such comparisons, especially when they receive the sanction of so high an authority. We think both electric lighting and electric traction have sufficient inherent good qualities, not only to occupy an open field, but to supplant the old systems; but in the latter case the work will be more slowly performed than in the former.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CABLES.

Sir,—Our attention has been called to a circular issued by Messrs. W. T. Glover and Co. descriptive of "Glover's patent high-conductivity lock armour," which is claimed by that firm to be their invention, and to the article in your last week's issue dealing with this cable. We give you notice that this is an infringement of the lock-coil patents which were issued to Messrs. Latch and Batchelor in 1884, which patents are the property of Messrs. George Elliot and Co., the well-known colliery owners and wire-rope makers of Westminster, Cardiff, and Newcastle-on-Tyne, who have granted us the exclusive right to use this invention in connection with electric cable work in this country.

Very large quantities of this lock cable have been made during the past 10 years for haulage and other purposes by Messrs. Elliot, and its advantages are fully appreciated by mining engineers. We have already manufactured many miles of cable under our license with lock-coil armour—in some cases the steel segments serving merely as a mechanical protection, in others the armouring being used as the return conductor; and we have no intention to allow our rights under these patents to be infringed. Our solicitors are taking the necessary steps for our protection; and we desire to give public notice that we shall take proceedings against any firm manufacturing, or against any person, company, or corporation using cables any part of which is formed of segments which, when put together, interlock so as to form a complete locked ring or shield on the cable, or otherwise infringing the patents in question.

We shall be obliged by your giving to this letter equal publicity to that given to the notice of Messrs. Glover in your last week's issue.—Yours, etc.,

T. O. Callender, Managing Director.

Callender's Cable and Construction Company, Limited,
90, Cannon-street, E.C., September 17, 1896.

THREE-PHASE MACHINERY AT THE BUDAPEST EXHIBITION.*

BY ALFRED O. DUBSKY.

There are two three-phase generators exhibited, each of 200 h.p. capacity, at 250 revolutions per minute. The distribution of the three-phase current is made at the pressure of 300 volts between two conductors, and the motors are wound directly for this voltage. One of these dynamos works at this same pressure, so its current can be used, therefore, directly for power distribution. The other generator is wound to give 3,000 volts, and several step-down transformers provide the low-tension network with current. The number of periods is always 42 per second. As even the smallest motors never have less than four poles, the highest number of revolutions at the motor shaft is only about 1,200 per minute.

Figs. 1 and 2 give two vertical sections through this generator. There are no revolving conductors, as the revolving part consists of a star wheel made of cast steel, with projecting poles composed of laminated iron. There are 10 such poles on each side of the machine. In this way the generator has two distinct armatures, each provided with an independent winding. The exciting coil is coaxial with the generator shaft, and by sending a continuous current through this coil a magnetic flux will pass through the winding of both armatures, according to the momentary positions of the projecting poles of the revolving part. These projections have a relative displacement on the two sides of the generator, and this displacement is equal to half the width of two projections. It will be quite apparent that the induced E.M.F. in the two distinct armature windings will have a relative difference of phase of exactly 90deg. By using now the well-known arrangement proposed by Mr. C. F. Scott, it is quite easy to obtain three equal E.M.F.'s with a phase difference of 120deg. For this purpose one armature is wound directly for a tension of 300 volts between its two terminals. The other armature has a number of turns 0·867 times less than the former armature, and as the sections of iron are exactly equal in both armatures, there will be an equal magnetic flux passing through the bobbins of both windings; the tensions will be, therefore, in the ratio of the number of turns. We now connect the terminal of one armature (with the smaller number of turns) to the middle of the winding of the other one, and the three remaining terminals will allow the commutation of three-phase currents.

There are great advantages to be obtained by using this arrangement. If there should be three distinct series of coils to generate the three-phase current, the machine would be far more complicated and expensive. In this way the costs of punching and the number of coils are less, for the number of poles is only twice as large as the number of the pole projections. Moreover, the crossing of the connections is completely avoided, which is a great advantage for high-tension work. Most of the three-phase generators manufactured by the different firms have just this latter fault. In the present construction the bobbins are wound quite separately and are slid on the several armature poles. They are held in their places by the use of wooden wedges; the insulation of the iron parts of the machine is made of thick sheets of micanite.

The further construction of this generator is clearly demonstrated in Figs. 1 and 2. The continuous-current exciter is connected directly on the generator shaft in such a way that the complete armature is built on a sleeve, which latter is keyed on the shaft without the use of any external bearing. This machine is driven by ropes from its steam-engine; the other mentioned three-phased generator of the same size is coupled directly to its steam-engine.

* From the *Electrical Engineer* (New York).

Digitized by Google

All these machines work with a considerably more magnetic flux than the special lighting generators. Without changing anything in the exciting current the drop of voltage between no load and full load on motor circuits never exceeds 15 or 20 per cent., while the short-circuit current is about 4·5 to 5 times larger than the current at full load. These machines are constructed for the use of motor circuits; for lighting purposes it is always more advantageous—for reasons of security—to employ dynamos having more copper and less iron in the armature.

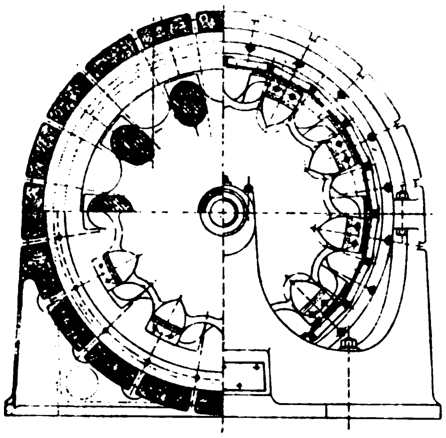

Fig. 1.

The special construction of these generators renders it possible to obtain also single-phase currents from them. One armature always generates single-phase currents, for it is only by the combination of both armatures that three-phase currents are produced. One 200-h.p. three-phase dynamo at the exhibition has been charged with 90 kilowatts in one armature, and is still employed at times to supply single-phase lighting current. Moreover, single-phase and three-phase currents can be produced at the same time by these dynamos. It would be then a true "monocyclic" installation, with the difference, that one entire armature is employed distinctly for the services of the "teaser coil."

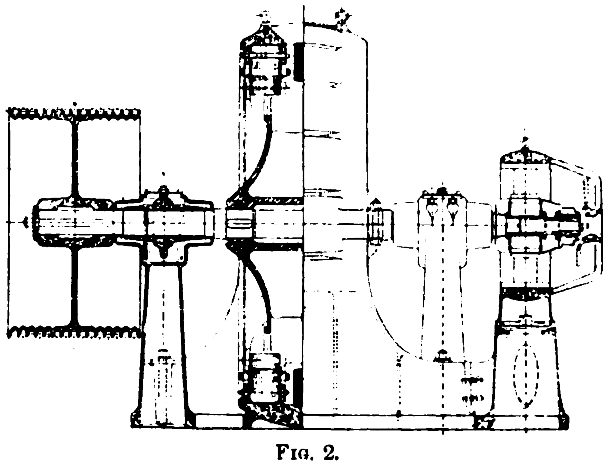

Fig. 2.

All these motors are of very different sizes. The smaller motors up to 8 h.p. have a rotor with a short-circuited armature and are switched directly on the circuit. The starting current under full load is about three times the current used when remaining at full load, and the starting torque is somewhat larger than the torque at normal running. The larger motors, those above 8 h.p., are of a different construction. In order to diminish the starting current and increase the starting torque, the inductors revolve and the induced armature is stationary, the latter having a diphase winding in order to diminish the variations of the torque in the different positions of the armature. A fluid rheostat is used to introduce large resistances during the starting, and these resistances are cut out afterwards from the circuit in proportion as the number of revolutions of the motor increases. These motors are suited to direct high-tension work, and an efficient plant is easily obtained with them.

APPLIED ELECTRO-CHEMISTRY.*

BY JAMES SWINBURNE.

LECTURE I.

Introduction.

There is probably no branch of industry which is developing so rapidly as electro-chemistry. It might have been thought that this development would have begun 10 years ago, as the electrical engineer was then quite able to provide economical steam dynamos. As a matter of fact, inventors have been working at electrolysis and electro-chemical processes for more than half a century, but a large portion of these were unpractical, as is sufficiently proved by their working out methods involving cheap electrical power when there was no prospect of such a thing. For the last 10 years or so, the applications of electricity to chemical manufacture, and to metallurgy, have engaged the attention of a great many very able people, and a still greater number of the class the Americans expressively call "cranks." A considerable time-lag was to be expected, for it takes quite 10 years for people to realise that electrical power can be developed at high efficiency and low cost. Even now the average mechanical engineer does not appreciate the value of the electric motor; so it is hardly to be expected that chemical manufacturers can yet all fully realise exactly what electrical power will do. All the same they have been by no means behindhand, and there are several large electro-chemical works already running in different parts of the world.

Some years ago the difficulty was that the average electrician knew no chemistry, and the chemist knew nothing about electricity; so that there was a sharp line between electricians and chemists. There is, however, a new state of things arising. During the last 15 years a new science may be said to have come into existence. This is chemistry on an engineering basis—that is to say, chemistry is now studied in its relation to the transformation of energy. This study demands almost a peculiar training. It requires a knowledge of mathematics and of thermo-dynamics, and mathematics is not generally a strong point among chemists. It also needs a knowledge of electricity, and of general physics, and, of course, of chemistry. The result is that what I have called engineering chemistry, or chemical energetics, is not the work of the older chemists, or physicists, but, with few very eminent exceptions, is largely in the hands of a number of comparatively young men who are not trammelled by older ideas, and who are specially fitted by their training in chemistry, physics, and mathematics to deal with this subject.

Splendid work has been recently done in physical chemistry and the theory of electrolysis in Germany, and that country has distinctly taken the lead in both theoretical and applied electro-chemistry. But the result is that there is a gradual development of two distinct classes of electro-chemist. One the purely scientific, who does not know the price of anything, and could not tell a buddle from a jigger; and the other who never heard of the Kupferferrocyanidniederschlagsmembranerscheinungen — I think that word is approximately correct. It is men of the last class that are doing the practical invention, and are getting capital and setting up factories. But the first class must not be regarded as useless. Like all purely scientific men, they are providing the raw material for the practical technologist to work up into the finished article for the use of man. It is, however, a great misfortune that the two kinds of knowledge cannot be more often combined in the same man; and the present tendency is towards more complete separation, which is to be deplored.

Electricity is being gradually applied to many branches of metallurgy, and to various process of chemical manufacture, chiefly inorganic; there are also signs of its development directly and indirectly in the manufacture of organic products. Electricity is also used as a means of getting very high temperatures in the electric furnace, and though in such cases the reaction is generally a mere reduction by carbon and not electrolysis at all, their description may be classed under electro-chemical work.

It would be clearly impossible to give any account of even the theory of electrolysis, or the practice of it alone, in four short lectures. It was, therefore, very difficult to know how to give a short course on such a subject. As experiments are an important feature in the Cantor lectures, and as the only conceivable reason for anyone's coming to a lecture—unless he has to give it—is to see experiments which he cannot see elsewhere, and which cannot very well be described in print, it seem best to show as many experiments as possible. The subject, however, does not lend itself very well to lecture demonstration, and, therefore, as many experiments as possible—especially new ones—were chosen, and the lectures were arranged and delivered very much to suit the experiments. As these would hardly read well, the printed lectures are different, and include very little of the delivered matter, being

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

practically independent. As just explained, it would be impossible to go over the whole ground even very shortly; so I will merely touch on a few points that seem to me interesting, without attempting to follow the lectures delivered, or to give any sort of general survey of the subject. Up to now, the Cantor lectures have been not only exceedingly valuable in themselves, but the lecturer has frequently changed into an author, and the series of lectures grown into a book. If it is ever my fortune to develop these lectures into a book, I shall then at least have room to give a more general account of the subject.

Cost of Energy.

In most electro-chemical manufactures the cost of energy is of cardinal importance. The cost and heating power of the coal is the most important factor. If coal is taken at 10s. a ton, and gives half an indicated horse-power hour per pound, and if the combined efficiency of the engines and dynamos is taken at 80 per cent., the coal comes out at 0·18d. per kilowatt-hour. In many places coal is much cheaper than 10s. per ton, without being anything like proportionally worse, so that 0·18d. per Board of Trade "unit" may be taken as quite liberal enough, as far as coal goes. To the cost of coal must be added labour, superintendence, oil, and waste, and the interest and depreciation on the generating plant. These can be covered with a reasonable margin by taking the cost of power as a farthing per kilowatt-hour. A great deal depends, however, on precisely what is meant by cost. A farthing per kilowatt-hour covers outlay for coal, wages, and stores, and interest and depreciation at low rates on capital and plant. If, however, an engineer were to get out an estimate for the manufacture of some chemical which was very simple, needing little more than electrolytic tanks and storage and packing, and if he found that the vats and electrolytic department cost, say, £16,000 to build and £4,000 as working capital, and that the profit after paying salaries, wages, rent, taxes, office expenses, and after paying for all energy used at the rate of a farthing a kilowatt-hour, was £2,000 a year, he would be quite wrong in saying it would pay 10 per cent. The capital in engines and dynamos must be taken into account and added to the other, bringing it up to, say, £40,000. Then to the £2,000 must be added the interest on the £20,000 in generating plant, that is included in the farthing, say £1,000. The total profit is thus £3,000 on £40,000, not £2,000 on £20,000; or 7½ per cent. instead of 10.

This example is given to show that a good deal of care is necessary in working out even the roughest estimates. The great difficulty is to know what is meant by cost in each case. If the generating plant belonged to an independent proprietor, he would not be likely to supply energy at a farthing per kilowatt-hour. He would reckon his prime cost as a little less than a farthing, and would then add on a considerable percentage to give his selling price. In central-station work the cost of energy is enormously greater. This is because the generation does not go on continuously day and night, and because the expenses of distribution and collection as well as the inconveniences of location come in. The cost of energy produced by an electric light station is thus no criterion, as the other expenses run up so enormously that the cost of coal burnt at full economical load is almost buried under a pile of incidental expenses.

Probably the greatest errors in estimating the costs of electrolytic processes are due, not to under-estimating or over-estimating the cost of electrical energy, but to not realising the expenses of handling, packing, finishing, or perhaps purifying the materials. Other things have to be considered, such as the dislike of the trade to anything new or apparently new. The word "electric" acts like magic in increasing the sale of hair-brushes, quack medicines, and a thousand and one things which have nothing to do with electricity; but these articles are mostly sold to women, or to the more ignorant classes. In commerce, on the other hand, there is an equally ignorant prejudice again anything electric. Electrically tanned leather, for example, is regarded with considerable suspicion, especially as it is somewhat lighter in colour. Even the packing should be the same as that of the goods made in the old way. Some day people may realise that electrolytically-made chemicals are often more nearly pure than others. This is already commonly understood in the case of high-conductivity copper; but then it is chiefly bought by electrical engineers.

In dealing with the cost of electrical energy, the price of coal has here been taken as the basis. There is abundance of water power, however, in many districts, and we must consider how far that may affect the question of cost of manufacture. It is only too frequently assumed that water power costs nothing, and must, therefore, give electro-chemical manufacture an enormous advantage over older processes. This is very far from the truth, however, and the economy to chemical workers of the use of water power has been enormously exaggerated. I say the economy to chemical workers advisedly, for I do not mean that it does not pay well to utilise water power, but that the advantage is to the owner of the waterfall, not to the manufacturer, except in special cases. An example will illustrate this best. Imagine a chemical district where coal is 10s. a ton, and where there is a large use of electrical power, say, for making caustic and bleach electrolytically. Imagine, also, that there is water power in the neighbourhood. If the owners of a chemical works want power, they will apply to the proprietor of the waterfalls. He will by no means make them a present of as much power as they want; on the contrary, he will charge rent; and he will charge as high a rent as he thinks he can get. The chemical makers, on the other hand, will not give a rent that will make the water power as costly as coal, but they will be guided by the least difference, so that the rent asked and obtained will be such that it costs the chemical company the same for water as for steam power. If the turbines and races which we suppose to be put down by the chemical manufacturers cost about the same as the engines and boilers, and take about the same labour and superintendence as the steam-generating plant, the rent for the water power, apart from the land for the turbine and dynamos, which is a different matter, will be approximately equal to the cost of coal for the same power. Assuming the plant to run continuously day and night, 1,000 kilowatts generated at 80 per cent. efficiency at 2lb. of coal per kilowatt-hour, coal being 10s. a ton, comes to £6,500 a year in round numbers, or £6. 10s. per kilowatt-year. A water power of, say, 10,000 kilowatts in such a place thus corresponds to a coal mine whose yearly output of coal is worth £65,000 before it is touched in the mine, and whose supply of coal is inexhaustible.

Suppose, however, that the water power is not in the chemical district at all, but in such a place as, for instance, Norway. The chemical manufacturer may be at some advantage there. The district may be inaccessible, and the establishment of works there may involve special difficulties and expense. In such a case the proprietor of the water power will not ask £6. 10s. per kilowatt-year, for he has no chance of getting that. He will eventually get some smaller rent, so that it will just pay a new concern to start in Norway rather than England. Still, it is the owner of the water power that gets the advantage from it, not the chemical manufacturer.

Whether it will pay to use water power in a given place or not depends on how far the power is an important item in the cost of manufacture. In such cases as making aluminium, carborundum, or calcium carbide, the power is by far the heaviest part of the cost of manufacture; and as carriage is a small matter is these cases, such manufactures will be the first to grow in places which have water power, but which are otherwise inconvenient. In most cases, however, the actual cost of the power is a comparatively small matter, and the inconveniences of being away from supply of raw material and coal for heating purposes, and from the market and the supply of skilled labour, make it inadvisable to use water power, even when it can be obtained at a very low rent. Cases like that of Niagara are peculiar. It seems to be the idea that an industrial centre will spring up around the Falls merely to batten on cheap power. There are not very many industries, electrical or non-electrical, in which power pays a very important part, and in most cases it would not pay to start works in a new locality, even if the power were given, as the drawbacks are serious. Thus, for example, it would not pay a cotton-spinner to start a new works in Devonshire, even if power were given him there, as he could not get operatives there, and he would be completely out of touch with his markets, both for buying and selling. In other cases, the works must be near the raw material, if it is heavy, as in the case of gold mining, or near coal, or near both, as in the case of ironworks. In the case of Niagara, it will undoubtedly pay users of electrical furnaces and makers of aluminium to take power from the supply company there rather than burn coal, as the supply company can always supply power more cheaply than it can be got from coal. Whether it would pay to go to Niagara, rather than to any other falls, depends on the terms offered.

The position of water powers is a little anomalous just at present, because things have not settled down yet. At present the water powers are not fully utilised, or anything like it; and there are very few processes in which power is the factor of paramount importance in determining the cost. At first, therefore, power can be got for such processes at nominal rents, and it is almost correct in such cases to say the power costs nothing. The farthing per kilowatt-hour, in the case of coal, however, included interest and depreciation on plant as well as labour and stores. In the case of the waterfall at a nominal rent, the interest on the capital sunk in flumes, races, turbines, and dynamos must also be taken into account. The cost of power will then come out a long way below a farthing, unless the fall of the water is very slight, and there are considerable engineering difficulties. In cases like aluminium or calcium carbide, carriage is of little importance. The bauxite or other oxide of aluminium has to be carried in any case, and if it has to go by sea or rail, it does not much matter how far it goes within reason, provided it has not to be handled on the way. The aluminium or the calcium carbide is so valuable in proportion to its weight, that the carriage of the produce to market is not worth considering. There are any number of waterfalls in the United

Digitized by Google

States, Canada, Switzerland, and Norway which are available for processes of this nature, so it is probable that such processes will be able to obtain water power at very low rents for very many years to come.

Turning now to such cases as, for instance, making bleaching powder and caustic soda by the electrolysis of a solution of salt, the number of waterfalls available for this purpose is comparatively small. Suppose the electrolysis vats have a current efficiency of 80 per cent., and take, say, six volts per vat, the cost of energy comes out approximately £5 per ton of caustic. Of course, this cost must be allocated as to the caustic and bleaching powder, as they are not independent products. We may say £2. 10s. per ton of caustic, and £2. 10s. for 2·3 tons of bleach, or, roughly, £2. 10s. for caustic and £1 a ton for bleaching powder. Even if the whole of this were saved, it would not pay to start a works in an out-of-the-way mountain pass, where the carriage of salt, lime, and coal for finishing, and that of the finished caustic and bleach, would come to far more than £5 for each ton of caustic made. In addition to carriage, superintendence, and skilled labour are more expensive in out-of-the-way districts. The whole object of life is not to make an income ; that is only a means to an end, and a man with anything in him will not exile himself except as a temporary way of making money comparatively rapidly.

The number of water powers at the coast, or in other very accessible places is limited, and there will soon be enough taken up to raise the rent till the chemical manufacturers no longer profit appreciably by it. The result is that in the immediate future water power will not help the electro-chemist except in such cases as the electrical furnace.

At present water powers are sometimes to be got cheap, as the owners having so far got nothing for them are glad to sell outright, or to give a concession for a number of years for a certain income, rather than await the chances of high rents later on, when electro-chemistry is more developed. In other cases proprietors have already very exaggerated ideas of the value of their property, and it is impossible to deal with them. It is almost needless to add that if an electro-chemical company owns a waterfall, it is not in any better position than if it rented it. It has merely sunk some of its capital in the waterfall, and the same rent that would otherwise have to be paid should be charged against the manufacturing account, and credited to the profit account of the waterfall ownership. If the waterfall was bought cheap, owning it may be profitable, but it does not cheapen the electrolysis, as the company might just as well have let their waterfall for a fair rent and started their works in St. Helens or Kalk. It is needless to say all this is merely elementary economics. I do not carry books on economics with me on a holiday; but if I remember right, it is a simple application of Ricardo's theory of rent.

While on the subject of costs it may be as well to mention an apparent anomaly which often comes up in making estimates or designing new works. Suppose a process is to be worked which needs a large steam-generating plant, and suppose that on paper the process is capable of yielding an enormous profit, say 50 per cent., on the capital. It may be safely said that such a process, in practice, will not yield such a large profit, as all sorts of things will go wrong, and troubles will arise in unexpected quarters. Let us assume, then, that in practice even a pessimist, who knows his subject, expects a profit of 25 per cent. to be earned. Then the question arises, what sort of machinery is to be put down? As the engines are to run day and night, the efficiency of the generating plant seems of the highest importance, and the first idea is to put down high-class boilers, with automatic stokers, and triple-expansion condensing engines of the best and most modern types, on the ground that, as the engines run continuously, the saving in coal is more than equal to the interest on the extra capital sunk. It must be remembered, however, that the available capital is limited, as, however good the process appears, it is of necessity a large experiment at first. Unless, therefore, the saving by coal will pay at least the same interest on the increased capital as the process will as a whole, it will be better to spend it so as to get a larger output at a lower efficiency. In extreme cases, it may even pay to fit up second-hand marine or other engines at low cost and low efficiency. The same considerations apply to other kinds of plant. In such cases economical working is not so important as it appears at first sight, but freedom from breakdown is of course vital. Old machinery is often very safe from this point of view, if not overworked. When the process is satisfactorily started, and more capital is available, and the profits are falling towards the normal, it will pay to put in the best machinery, and to work at the highest economy, giving the plant a term of many years to repay its extra cost.

While on the subject of costs and estimates, it may be as well to point out another consideration that is frequently overlooked. An electro-chemical process is proposed which is to compete with a large existing chemical industry, and it is assumed that the price will not fall, because if it did fall a little, the chemical manufacturers would fail. The existing steady price of a chemical is such that the badly-managed concerns just make it pay, and the well-managed works make good profits. The better makers can always lower prices considerably without loss, so that a new mode of manufacture cannot command the market by being able to produce a little cheaper ; it can only oust a few of the existing manufacturers. It must be remembered that it will not pay to put down plant for a process that cannot pay interest and depreciation on that plant; but the old makers have already put down their plant, and rather than close as prices fall, it will pay them to write off the whole of their plant as worthless, or rather at its break-up value, and go on, if they make any profit on their working expenses alone, or even if they hope to do so soon. Before a new process can therefore drive an old one out of the market, its profits must at least be greater by the interest, and for some time by the depreciation of the plant engaged in the old manufacture in addition.

Theory.

But little can be said here on such a subject. For most practical purposes, electrolysis may be regarded as a convenient means of bringing about oxidation and reduction. The words oxidation and reduction are used very loosely by chemists, but the idea is generally clear enough. If we wanted to make it still clearer, we might go so far as to describe oxidation as what goes on at the anode and reduction as what takes place at the cathode. This would give a good idea of the changes meant, and the notion could then be extended to reactions which cannot be, or, at any rate, are not produced by electrolysis.

When we examine the processes employed in commercial chemical manufacture, as well as in the laboratory, we are struck by the fact that by far the largest portion are processes of oxidation and reduction. Nearly all the processes for getting metals consist of reductions. Iron oxide is reduced to get iron. The carbon is then oxidised out in the converter or on the puddling hearth, to get steel or wrought iron. Zinc sulphide is oxidised first, merely to get it into a form to which reduction is easily applicable. The reduced zinc is then again oxidised, to make white paint. The Leblanc process for making soda crystals and bleach is a maze of oxidations and reductions, with a few substitutions thrown in. The pyrite is oxidised into oxide and sulphur dioxide. There are alternate reductions and oxidations of a complicated nature going on in the acid chambers. The sulphuric acid acting on the salt is a substitution process. Generating chlorine from the muriatic acid is an oxidation and reduction process, and the absorption of chlorine by lime may be considered another case. The bleach is then sold to oxidise paper pulp, and frequently to oxidise our linen to a regrettable extent. The salt cake is reduced in the black ash revolvers, a substitution going on also, this reaction being really very complicated, and after that there is only lixiviation and crystallisation. It would weary the reader, or we might include the Weldon process as part of the system, and enumerate more oxidations and reductions. We may, however, imagine the carbonate to be reduced by carbon, to give us sodium ; and we now have a system, involving, without the Weldon process, no less than five separate oxidation and reduction processes to split salt into chlorine and sodium. Electrolysis splits fused salt into chlorine and sodium at once, without any other processes or chemicals being needed, and without any waste. The difficulties in electrolysing fused salt are so great, however, that at present the older and tremendously roundabout processes hold the field. The electrolysis of salt solution is more complicated as sodium is not obtained, and there are a number of small secondary reactions.

For many purposes, all that the electro-chemist—if such a word could be applied to such a man—wants to know is, how much of a compound is decomposed by a coulomb or an ampere-hour, and what pressure is needed. Faraday's law gives him one of the data ; the other is a different matter, as the pressure needed depends not only on the back pressure of the decomposition vat, but also on the resistance of the circuit. The resistance often depends on the current density ; for instance, if bubbles of gas are being evolved from an electrode, they insulate it, except for the thin films of liquid separating them. The result is a very high surface resistance. I have tried the effect of gradually increasing the pressure on lead plates in dilute acid. The pressure and current rise together until something like three volts is reached. The current then increases much more rapidly than the pressure, gases being given off in abundance, and between three and four volts there is a state of things in which a very small difference of pressure produces a given change of current density. The arrangement was used in connection with a resistance in a differential governor and was very sensitive. As many processes, such as electrolysis of salt solution, involve evolution of gases at the electrodes, it is important to get the most economical results. The mistake is often made in designing vats with electrodes inconveniently close together with the idea that a substantial reduction of the resistance is thus secured. When there must be evolution of gas at an electrode the majority of the resistance is at the electrodes, and it generally make little difference how far the electrodes are apart within reason.

THE BRITISH ASSOCIATION.

Address to the Mechanical Science Section.

BY SIR DOUGLAS FOX (VICE-PRESIDENT, INSTITUTION OF CIVIL ENGINEERS), PRESIDENT OF THE SECTION.

It is rather over a quarter of a century since the British Association last held its meeting in the hospitable city of Liverpool. The intervening period has been one of unparalleled progress, both generally and locally, in the many branches of knowledge and of practical application covered by civil and mechanical engineering, and therefore rightly coming within the limits for discussion in the important section of the association in which we are specially interested. During these 25 years the railway system of the British Isles, which saw one of its earliest developments in this neighbourhood, has extended from 15,376 miles, at a capital cost of £552,680,000, to 21,174 miles, at a capital cost of £1,001,000,000. The railway system of the United States has more than trebled in the same period, and now represents a total mileage of 181,082, with a capital cost of 11,565,000,000dol. The Forth and Brooklyn, amongst bridges, the Severn and St. Gothard, amongst tunnels, the gigantic works for the water supply of towns, are some of the larger triumphs of the civil engineer; the substitution of steel for iron for so many purposes, the perfecting of the locomotive, of the marine engine, of hydraulic machinery, of gas and electric plant, those of the mechanical branch of the profession.

The city of Liverpool and its sister town of Birkenhead have witnessed wonderful changes during the period under review. Great and successful efforts have been made to improve the watergate to the noble estuary, which forms the key to the city's greatness and prosperity; constant additions have been made to the docks, which are by far the finest and most extensive in the world. The docks on the two sides of the river have been amalgamated into one great trust. In order properly to serve the vast and growing passenger and goods traffic of the port, the great railway companies have expended vast sums on the connections with the dock lines and on the provision of station accommodation, and there have been introduced, in order to facilitate intercommunication, the Mersey Railway, crossing under the river, and carrying annually nearly 10 millions of passengers, and the Liverpool Overhead Railway, traversing for six miles the whole line of docks, and already showing a traffic of 7½ millions of passengers per annum. A very complete waterside station connected with the landing-stage has been lately opened by the Dock Board in connection with the London and North-Western Railway. In addition to this, the water supply from Rivington and Vyrnwy has now been made one of the finest in the world.

The following comparative figures, kindly supplied by Mr. K. Miles Burton, may be of interest:

	1871		1895.
Population of Liverpool	493,405	...	641,000 (estimated)
Population of Birkenhead	65,971	...	109,000 (estimated)
Area of docks, Liverpool, about	236 acres		362½ acres
Area of docks, Birkenhead, about	147 acres		160 acres
	383		522½
Number of steamers using the port	7,448	...	18,429
Average tonnage of six largest vessels entering the port	2,890	...	6,822

The following figures show the importance of the local railway traffic:

	1895
Number of passenger stations within the boroughs......	58
Number of goods stations	50
Number of passengers crossing the Mersey in the 12 months (Woodside Ferry)	7,143,088
Number of passengers crossing the Mersey in the 12 months (Mersey Railway)	6,976,299

To the hydraulic engineer there are few rivers of more interest and presenting more complicated problems than the Mersey and its neighbours, the Dee and the Ribble. They all possess vast areas of sand covered at high water, but laid dry as the tide falls, and in each case the maintenance of equilibrium between the silting and scouring forces is of the greatest importance to the welfare of the trading communities upon their banks. The enclosure of portions of the areas of the respective estuaries for the purposes of the reclamation of land, or for railway or canal embankments, may thus have far-reaching effects, diminishing the volume of the tidal flow and reducing the height of tide in the upper reaches of the rivers. Some idea of the magnitude of these considerations may be derived from the fact that a spring tide in the Mersey brings in through the narrows between Birkenhead and Liverpool 710 millions of cubic yards of water to form a scouring force upon the ebb. The tidal water is heavily laden with silt, which is deposited in the docks, and, at slack water, upon the sandbanks. The former is removed by dredging, and amounts to some 1,100,000 cubic yards per annum; the latter is gradually fretted down into the channels and carried out to sea before the ebb. Whilst a considerable portion of the narrows is kept scoured, in some places right down to the sandstone rock, there is a tendency, on the Liverpool side, near the landing-stage, to silt up, a difficulty counteracted to some extent by the extensive sluicing arrangements introduced by Mr. George Fosbery Lyster, the engineer of the Mersey Docks and Harbour Board.

Very extensive and interesting operations have been carried on by the Board in connection with the bar at the mouth of the river. Dredgers specially designed for the purpose have been employed for some six years, with the result that 15,142,600 tons of sand and other dredged matter have been removed, and the available depth of water at low water increased from 11ft. to 24ft. in a channel 1,500ft. in width. Those who have made the Transatlantic passage in former years can more readily appreciate the very great advantage accruing from this great improvement. Formerly, vessels arriving off the port on a low tide had to wait for some hours for the water-level to rise sufficiently to enable them to cross the bar; the result of a large vessel lying outside, rolling in the trough of the sea with her engines stopped, was that not infrequently this proved to be the worst part of the voyage between New York and Liverpool, and passengers who had escaped the malady of sea-sickness throughout the voyage were driven to their cabins and berths within three or four hours of landing. Owing to the very successful dredging operations ships of largest size can now enter or depart from the Mersey at any state of the tide, and they are also able to run alongside the landing-stage without the intervention of a tender. Such vessels as the "Teutonic" or "Majestic," of nearly 10,000 registered tonnage, 566ft. in length, 57ft. wide, and 37ft. deep; or the still larger vessels, the "Campania" or "Lucania," of nearly 13,000 tons register, 601ft. in length, 65ft. in width, and 38ft. in depth, can be seen, on mail days, lying alongside.

Whilst the estuary of the Mersey presents a narrow entrance with a wide internal estuary, the Dee, owing to extensive reclamation of land in the upper reaches, has a wide external estuary leading to an embanked river of very limited width, up which the tide rushes with great velocity laden with silt, rising in some two hours, then, during a short time of slack water, depositing the silt, which is not removed by the ebb tide, spread over some 10 hours, and therefore having comparatively little velocity. In this case also the outer estuary shows a great tendency to silt up beyond the reach of any but the highest spring tides. The reclamation of the Ribble has not yet proceeded so far as to so seriously affect the general conditions of the estuary, but here also there is a constant tendency in the channels to shift, and the erosion which takes place when a high tide and wind combine is very remarkable. A most important improvement was introduced in 1886 by Mr. G. F. Lyster, when it was decided to raise the water-level in certain of the docks by pumping, the wharves being heightened in proportion, and half-tide basins, or locks, made use of to compensate for the difference of level.

The area of the docks so treated in Liverpool is 78 acres, whilst at Birkenhead the whole area of the docks on that side of the river, amounting to 160 acres, is so raised. The hydraulic power used in the docks is very large, the indicated horse-power of the engines amounting to 1,673 in the case of Liverpool, and 874 in that of Birkenhead; whilst the Hydraulic Power Company are supplying some 1,000 h.p. to railways and private firms. The direct-acting hydraulic lifts of the Mersey Railway have now been at work for 10 years, and through these, at St. James's Station, no less than 75,000,000 to 80,000,000 of passengers have passed with regularity and safety.

It is remarkable that whilst Great Britain led the van in the introduction of steam locomotion she has lagged in the rear as regards electric and other mechanical traction. This arose in the first instance, from mistaken legislation, which strangled electrical enterprise, which is still much hampered by the reluctance of public authorities to permit the introduction of the necessary poles and wires into towns. At the date of the latest published returns there were at work in the United States no less than 12,133 miles of electric, in addition to 599 miles of cable, tramway. Hardly a large village but has its installation, and vast have been the advantages derived from these facilities. In Brooklyn, one company alone owns and works 260 miles of overhead trolley lines. With the exception of some small tramways at Portrush, Brighton, Blackpool, South Staffordshire, Hartlepool, etc., the only examples in this country of serious attempts to apply E.M.F. to the carriage of passengers are the City and South London Railway and the Liverpool Overhead Railway, the latter being the latest constructed, and having, therefore, benefited by the experience gained upon the London line. This railway is over six miles long, a double line of the normal, or 4ft. 8½in. gauge, running on an iron viaduct for the whole length of the docks; the installation is placed for convenience of coal supply about one-third of the distance from the northern end. Particulars of this interesting work will be placed before the section, but suffice it to say that a train service of three minutes each way is readily maintained, with trains carrying 112 passengers each, at an average speed of 12 miles per hour, including stoppages at 14 intermediate stations. During the last year, as before stated, 7½ million passengers were carried, the cost of traction per train mile being 3.4d. The Hartlepool tramway is proving successful, overhead trolleys and electric traction having taken the place of a horse tramroad, which was a failure from a traffic point of view. Careful researches are being prosecuted and experiments made with the intention of reducing the excessive weight of storage batteries. If this can be effected they should prove very efficient auxiliaries, especially where, in passing through towns, underground conductors are dangerous, and overhead wires objectionable.

In connection with electric traction it is very important to reduce, if possible, the initial force required for starting from rest. Whether this will be best attained by the improvement of bearings and their better lubrication, or by the storage, for starting purposes, of a portion at least of the force absorbed by the brakes, remains to be seen, but it is a fruitful field for research and experiment. In the United States there is a very general and rapid displacement of the cable tramways by the overhead-wire electric system. The latter has many opponents, owing probably to causes which are preventible. Many accidents were caused by the

Digitized by Google

adoption of very high-tension currents, which, on the breakage of a wire, were uncontrollable, producing lamentable results. The overhead wires were placed in the middle of the street, causing interference with the passage of fire escapes. The speed of the cars was excessive, resulting in many persons being run over. The cable system therefore found many advocates, but the result of experience is in favour of electrical traction under proper safeguards. The cable system can only compete with the electric system when a three-minute or quicker service is possible, or, say, when the receipts average £20 per mile per day; it is impossible to make up lost time in running, and the cars cannot be "backed." If anything goes wrong with the cable, the whole of the traffic is disorganised. The cost of installation is much greater than in the case of electricity, and extensions are difficult. On the other hand, electricity lends itself to the demands of a growing district, and extensions are easily effected. It satisfies more easily the growing demands on the part of the public for luxury in service and car appointment. It is less expensive in installation, and works with greater economy. By placing the wire at the side of the street, and using a current of low voltage, the objections are greatly minimised, and the cars are much more easily controlled and manipulated. In cases of breakdown these are limited to the half-mile section, and do not completely disorganise the service. Electric cars have been worked successfully on gradients of 1 in 7. The conduit slot system can be adopted with good results, provided care is taken in the design of the conduit, and allowance made for ample depth and clearance. A width of ⅝in. is now proved to be sufficient. Where, however, there are frequent turnouts, junctions, and intersecting lines, the difficulties are great and the cost excessive. The following figures represent the cost of a tramway on this system in America:

Cost of track and conduit, per mile of single track..	£5,600
Insulator, boxes, and double conductor	480
Asphalte paving on 6in. of concrete to 2ft. outside double track....	1 500
	£7,580

Complete cost of operating four miles of double track for 24 hours per day with 2½-minute service, 4·55d. per train mile (exclusive of interest, taxes, etc.). One train consists of one motorcar and one trailer.

The trains make a round trip of eight miles in one hour, with three minutes lay-off at each end. The cost of keeping the slot clean comes to about £40 per quarter, and the repairs to each plough conductor about 50s. per quarter. Attempts have been made to obviate the necessity of the slot by what is known as the closed conduit; but at present the results are not encouraging. The following figures will help to convey to the mind the great development which is taking place in America, as regards the earnings upon lines electrically equipped. They are derived from the report of the State Board of Railroad Commissioners for Massachusetts:

	1888	1894	Increase.
Net earnings per passenger carried...	·48	·78	62·5 per cent.
Net earning per car mile	2·78	4·83	73·56 ,,
Net earning per mile of road	£484	£762	57 ,,

In addition to the application of electricity for illuminating purposes and for the driving of tramcars and railways, it has also been applied successfully to the driving of machinery, cranes, lifts, tools, pumps, etc., in large factories and works. This has proved of the greatest convenience, abolishing as it does the shafting of factories, and applying to each machine the necessary power by its own separate motor; the economy resulting from this can hardly be over-estimated. It is also successfully employed in the refining of copper and in the manufacture of phosphorus, aluminium, and other metals which, before its application, were beyond the reach of commercial application. The extent of its development for chemical purposes in the future no one can foresee. It is hardly necessary to call attention to the successful manner in which the Falls of Niagara and the large falls of Switzerland and elsewhere are being harnessed and controlled for the use of man and in which horse-power by thousands is being obtained. At Niagara single units of electrical plant are installed equal to about 5,000 h.p. output. These units are destined to be utilised for any of the purposes previously suggested, and it is computed that 1 h.p. can be obtained from the river and sold for the entire year day and night continuously for the sum of £3. 2s. 6d. per annum. Electric head-lights are being adopted for locomotives in the United States. The use of compressed air and compressed gas for tractive purposes is at present in an experimental stage in this country. The latter is claimed to be the cheapest for tramway purposes, the figures given being

Single-horse cars......	5⅝d.
Electrical cars, with overhead wires..........	4½d.
Gas cars	3½d.

Combination steam and electric locomotives, gasoline, compressed-air, and hot-water motors are all being tried in the United States, but definitive results are not yet published. The first electric locomotive practically applied to hauling heavy trains was put into service on the Baltimore and Ohio Railway in 1895 to conduct the traffic through the Belt Line Tunnel. It is stated that not only was the guaranteed speed of 30 miles per hour attained, but, with the locomotive running light, it reached double that speed. On the gradient of 8 per cent. a composite train of 44 cars loaded with coal and lumber, and three ordinary locomotives—weighing altogether over 1,800 tons—was started easily and gradually to a speed of 12 miles an hour without slipping a wheel. The voltage was 625. The current recorded was at starting about 2,200 amperes, and when the train was up to speed it settled down to about 1,800 amperes. The drawbar pull was about 63 000lb. The actual working expense of this locomotive is stated to be about the same as for an ordinary goods locomotive—viz., 23 cents per engine mile.

The rapid extension of tunnel construction for railway purposes, both in towns and elsewhere, is one of the remarkable features of the period under review, and has been greatly assisted by the use of shields, with and without compressed air. This brings into considerable importance the question of mechanical ventilation. Amongst English tunnels, ventilation by fan has been applied to those under the Severn and the Mersey. The machinery for the latter is probably the most complete and most scientific application up to the present time. There are five ventilating fans, two of which are 40ft. in diameter, and 12ft. wide on the blades; two of 30ft., and 10ft. wide; and one quick-running fan of 16ft. in diameter, all of which were ably installed by Messrs. Walker Bros., of Wigan. They are arranged, when in full work, to throw 800,000 cubic feet of air per minute, and to empty the tunnel between Woodside and St. James's-street in eight minutes; but, unfortunately, it is found necessary, for financial reasons, not to work the machinery to its full capacity. The intended extension of electrical underground railways will render it necessary for those still employing steam traction either to ventilate by machinery or to substitute E M F.

Great improvements have been lately made in the details of mechanical ventilators, especially by the introduction of anti-vibration shutters and the driving by belts or ropes instead of direct from the engine. The duties now usually required for mining purposes are about 300,000 cubic feet of air per minute with a water-gauge of about 4in.; but one installation is in hand for 500,000 cubic feet of air per minute with a water-gauge of 6in. Water-gauge up to 10in. can now be obtained with fans of 15ft. diameter only. An interesting installation has been made at the Pracchia tunnel on the Florence and Bologna Railway. The length of the tunnel is 1,900 metres, or about 2,060 yards; it is for a single line, and is on a gradient of 1 in 40. When the wind was blowing in at the lower end, the steam and smoke of an ascending train travelled concurrently with the train, thus producing a state of affairs almost unimaginable except to those engaged in working the traffic. Owing to the height of the Appennines above the tunnel, ventilation shafts are impracticable; but it occurred to Signor Saccardo that by blowing air by means of a fan into the mouth of the tunnel through the annular space which exists between the inside of the tunnel arch and the outside of the traffic gauge a sufficient current might be produced to greatly ameliorate the state of things. The results have been most satisfactory, the tunnel, which was formerly almost dangerous under certain conditions of, weather being now kept cool and fresh with but a small expenditure of power.

In an age when, fortunately, more attention is paid than formerly to the well-being of the men, the precautions necessary to be observed in driving long tunnels, and especially in the use of compressed air, are receiving the consideration of engineers. In the case of the intended Simplon Tunnel, which will pierce the Alps at a point requiring a length of no less than 12½ miles, a foreign commission of engineers was entrusted by the Federal Government of Switzerland with an investigation of this amongst other questions. During the construction of the St. Gothard Tunnel, which is about 10 miles in length, the difficulties encountered were of necessity very great; the question of ventilation was not fully understood, nor was sanitary science sufficiently advanced to induce those engaged in the work to give it much attention. The results were lamentable, upwards of 600 men having lost their lives, chiefly from an insiduous internal malady not then understood. But the great financial success of this international tunnel has been so marked as to justify the proposed construction of a still longer tunnel under the Simplon. The arrangements which are to be adopted for securing the health of the employés are admirable, and will surely not only result in reducing the death rate to a minimum, but also tend to shorten the time necessary for the execution of the undertaking to one-half. The quantity of air to be forced into the workings will be 20 times greater than in previous works. Special arrangements are devised for reducing the temperature of the air by many degrees, suitable houses are to be provided for the men, with excellent arrangements for enabling them to change their mining clothes, wet with the water of the tunnel, before coming in contact with the Alpine cold. Every man will have a bath on leaving, his wet clothes will be taken care of by a custodian, and dried ready for his return to work. Suitable meals of wholesome food will be provided, and he will be compelled to rest for half an hour on emerging from the tunnel, in pleasant rooms furnished with books and papers. This may appear to some as excessive care, but kind and humane treatment of men results not only in benefit to them, but also in substantial gain to those employing; them and the endeavour of our own authorities and of Parliament to secure for our own workpeople the necessary protection for their lives and limbs in carrying out hazardous trades and employments is worthy of admiration.

The great improvements in subaqueous tunnelling can be clearly recognised from the fact that the Thames Tunnel cost £1,150 per lineal yard, whilst the Blackwall Tunnel, consisting of iron lined with concrete, and of 25ft. internal diameter, has, by means of Greathead's shield and grouting machine, been driven from shaft to shaft a distance of 754 yards for £375 per yard. Tunnels have now been successfully constructed through the most difficult strata, such as water-bearing silt, sand, and gravel, and by the use of grouting under pressure subsidence can almost entirely be avoided, thus rendering the piercing of the substrata of towns, underneath property without damaging it, a simple operation, and opening

Digitized by Google

up to practical consideration many most important lines of communication hitherto considered out of the question. On the other hand, very little improvement has taken place in the mode of constructing tunnels in ordinary ground since the early days of railways The engineers and contractors of those days adopted systems of timbering and construction which have not been surpassed. The modern engineer is, however, greatly assisted by the possibility of using brindle bricks of great strength to resist pressure, combined with quick-setting Portland cement, by the great improvements which have taken place in pumping machinery, and by the use of the electric light during construction.

A question which is forcing itself upon the somewhat unwilling attention of our great railway companies, in consequence of the continual great increase of the population of our cities, is the pressing necessity for a substantial increase in the size of the terminal stations in the great centres of population. Many of our large terminal stations are not of sufficient capacity to be worked properly, either with regard to the welfare of the staff or to the convenience of the travelling public. Speak to station masters and inspectors on duty, when the holiday season is on, and they will tell you of the great physical strain that is produced upon them and their subordinates in endeavouring to cope with the difficulty. This, if nothing else, is a justification for the enterprise of the Manchester, Sheffield, and Lincolnshire Railway Company in providing an entirely new terminus for London. It is 30 years since the last, that of St. Pancras, was added, and during that period the population of London has increased by no less than two millions.

The discussion, both in and out of Parliament, of the proposals for light railways has developed a considerable amount of interest in the question. Experience only can prove whether they will fulfil the popular expectations. If the intended branch lines are to be of the standard gauge, with such gradients and curves as will render them suitable for the ordinary rolling-stock, they will, in many cases, not be constructed at such low mileage costs as to be likely to be remunerative at rates that would attract agricultural traffic. The public roads of this country (very different from the wide and level military roads of Northern Italy and other parts of the Continent) do not usually present facilities for their utilisation, and, once admitted, the necessity for expropriating private property, the time-honoured questions of frontage severance and interference with amenities will force their way to the front; fencing will be necessary, and, even if level crossings be allowed at public roads, special precautions will have to be taken. Much must then depend upon the regulations insisted upon by the Board of Trade. If, in consideration of a reduction in speed, relaxation of existing safeguards are permitted, much may no doubt be effected by way of feeders to existing main lines. If, on the other hand, the branches are of narrower gauge, separate equipment will be necessary, and transhipment at junctions will involve both expense and delay. It is very doubtful whether the British farmer would benefit much from short railways of other than standard gauge. He must keep horses for other purposes, and he will probably still prefer to utilise them for carting his produce to the nearest railway station of the main line or to the market town. The powers granted by the Light Railways Act, in the hands of the able commissioners appointed under the Act, cannot, however, fail to be a public boon. Special Acts of Parliament will be unnecessary, facilities will be granted, procedure simplified, some Government aid rendered, and probably the heavy burden of a parliamentary deposit will be removed.

It would seem quite probable that motorcars may offer one practical solution of the problem how best to place the farms of the country in commercial touch with the trunk railways, seaports, and market towns. They could use existing roads, could run to the farmyard or field, and receive or deliver produce at first hand. Such means of locomotion were frequently proposed towards the end of the last century, and in the early part of the present one, and it was not until the year 1840 that the victory of the railway over steam upon common roads was assured, the tractive force required being then shown to be relatively as 1 to 7. The passing of the Act of 1896, superseding those of 1861 and 1865, will undoubtedly mark the commencement of a new era in mechanical road traction. The cars, at present constructed chiefly by German and French engineers, are certainly of crude design, and leave much to be desired. They are ugly in appearance, noisy, difficult to steer, and vibrate very much with the revolutions of their engines, rising as they do to 400 per minute; those driven by oil give out offensive odours, and cannot be readily started, so that the engine runs on during short stops. There would seem to be arising here an even more important opening for the skill of our mechanical engineers than in the case of bicycles, in which wonderful industry the early steps appear also to have been foreign. It is claimed for a motorcar that it costs no more than carriage, horse, and harness; that the repairs are about the same; and that, whilst a horse, travelling 20 miles per day, represents for fodder a cost of 2d. per mile, a motorcar of 2½ h.p. will run the same distance at ½d. per mile. The highway authorities should certainly welcome the new comer, for it is estimated that two-thirds of the present wear and tear of roads is caused by horses, and one-third only by wheels.

Perhaps no invention has had so widespreading an influence on the construction of railways as the adoption of the Bessemer process for the manufacture of steel rails. This has substituted a homogeneous crystalline structure, of great strength and uniformity, for the iron rails of former years, built up by bundles of bars, and therefore liable to lamination and defective welds. The price has been reduced from the £13 per ton which iron rails once reached to £3. 15s. as a minimum for steel. There are, however, not infrequently occurring, in the experience of railway companies, the cracking and even fracture of steel rails, and the Government has lately appointed a Board of Trade Committee for the investigation incidentally of this subject, but specially of the important question of the effect of fatigue upon the crystallisation, structure, and strength of the rail. Experience proves, at any rate, that it is of great importance to remove an ample length of crop end, as fractures more frequently take place near the ends, aided by the weakening caused by bolt holes. Frequent examination by tapping, as in the case of tyres, seems, at present, the most effective safeguard. It is open to serious question whether the great rigidity of the permanent way of the leading railways of this country is an advantage. Certainly the noise is very great, more so than in other countries, and this points to severe shocks, heavy wear and tear of rails and tyres, and—especially when two heavy locomotives are run with the same train—liability to fracture. Whilst the tendency in this country and in the United States has been to gradually increase the weight of rails from 40lb. up to 100lb. per lineal yard, there are engineers who think that to decrease the rigidity of rail and fishplate, and weight of chair, and to increase the sleepers so as to arrive as nearly as possible at a continuous bearing, would result in softness and smoothness of running. The average and maximum speeds now attained by express trains would appear to have reached the limit of safety, at any rate under the existing conditions of junctions, crossover roads, and other interferences with the continuity of the rail. If higher speeds are to be sought, it would seem to be necessary to have isolated trunk lines specially arranged in all their details, free from sharp curves and severe gradients and probably worked electrically, although a speed of 100 miles per hour is claimed to have been reached by a steam locomotive in the United States.

The grain trade of the port of Liverpool has assumed very large proportions, and the system of storage in large silos has been adopted with great advantage, both as regards capital, outlay, and the cost of working per ton of grain. The Liverpool grain storage warehouses at Bootle will be open to members of the association, and there can be seen the latest development of the mechanical unloading, storing, and distribution of grain in bulk; the capacity is large, being

Warehouse No. 1,	56,000 tons	or 4,240,000 bushels;
,, ,, 2,	30,000 ,,	
Quay stores	20,000 ,,	

thus constituting this granary as one of the largest, if not the largest, in the world. The question of the pressure of grain is a very difficult one, and in constructing the brick silos, which are 12ft. across at the top, by nearly 80ft. in depth, large allowance has been made both for ordinary pressure and for possible swelling of the grain. The grain is unloaded by elevators, and then transported on bands, the result being its cooling and cleansing, as well as its storage and distribution.

The question of the early adoption in England of the metric system is of importance, not only to the engineering profession, but also to the country at large. The recommendation of the recent Royal Commission appointed for the consideration of the subject was that it should be taught at once in all schools, and that in two years' time its adoption should be compulsory; but it is much to be regretted that up to the present time nothing has been done. The slight and temporary inconvenience of having to learn the system is of no moment compared to the great assistance it would prove to the commercial and trading world; the simplification of calculations and of accounts would be hailed with delight by all so soon as they realised the advantages. England is suffering greatly in her trade with the Continent for want of it. Our foreign customers, who have now used it for many years, will not tolerate the inconvenience of the endless variety of weights and measures in use in England, and they consequently purchase their goods to a great extent from Germany rather than use our antiquated English system. It is no exaggeration to say that, with their knowledge of the metric system, they regard ours as completely obsolete and unworkable, just in the same way as we should were we to buy our corn, our wine, our steel and iron, by the hin, the ephah, or the homer, or to compute our measurements by cubit, stadium, or parasang. It behoves all who desire to see England regain her trade to use all their influence in favour of the adoption of this system, as its absence is doubtless one of the contributory causes for the loss that has taken, and is taking, place. An important argument in favour of the metric system of weights and measures is that it is adopted all over the civilised world by physicists and chemists; and it may be stated with confidence that the present international character of these sciences is largely due to this. It is interesting also to notice that the metric system is being gradually introduced into other branches of science. Anthropometric measurements made by the committees of the British Association in this country and in Canada are invariably given in metres, and a comparison with measurements made in other countries can be at once made.

The period of 25 years under review has indeed witnessed great advances, both in scientific knowledge and practical application. This progress has led to powerful yet peaceful competition between the leading nations. Both from among our cousins of the United States and from our nearer neighbours of Europe have we at this meeting the pleasure of welcoming most respected representatives. But their presence and the knowledge of the great discoveries made and colossal works carried out by them and their brother scientists and engineers, must make us of Great Britain face with increased earnestness the problem of maintaining our national position, at any rate in the forefront of all that tends towards the

Digitized by Google

"utilisation of the great sources of power in nature for the use and convenience of man." Those English engineers who have been brought in contact with engineering thought and action in America and abroad have been impressed with the thoroughness of much of the work, the great power of organisation, and the careful reliance upon scientific principles constantly kept in view, and upon chemical and mechanical experiments carried out often upon a much more elaborate scale than in this country. This is not the place from which to discuss the questions of bounties and tariffs, which have rendered possible powerful competition for the supply of machinery and railway plant from the Continent to our own Colonies, but there is certainly need for advance all along the line of mechanical science and practice if we are to hold our own—need especially to study the mechanical requirements of the world, ever widening and advancing, and to be ready to meet them by inventive faculty first, but also by rigid adherence to sound principles of construction, to the use of materials and workmanship of the highest class, to simplicity of design and detail, and to careful adaptation of our productions to the special circumstances of the various markets. It is impossible to forecast in what direction the great advances since 1871 will be equalled and exceeded in the coming quarter of a century. Progress there will, and must be probably in increased ratio, and some at the end of that period may be able to look back upon our gathering here in Liverpool in 1896 as dealing with subjects then long since left behind in the race towards perfection. The mechanical engineer may fairly hope for still greater results in the perfection of machinery, the reduction of friction, the economical use of fuel, the substitution of oil for coal as fuel in many cases, and the mechanical treatment of many processes still dependent upon the human hand. The electrical engineer (hampered as he has been in this country by unwise and retrograde legislation) may surely look forward to a wonderful expansion in the use of that mysterious force, which he has already learned so wonderfully to control, especially in the direction of traction. The civil engineer has still great channels to bridge or tunnel, vast communities to supply with water and illuminating power, and (most probably with the assistance of the electrician) far higher speeds of locomotion to attain. He has before him vast and ever-increasing problems for the sanitary benefit of the world, and it will be for him to deal from time to time with the amazing internal traffic of great cities. China lies before him, Japan welcomes all advance, and Africa is great with opportunities for the coming engineers.

Let us see to it, then, that our rising engineers are carefully educated and prepared for these responsibilities of the future, and that our scientific brethren may be ever ready to open up for them by their researches fresh vistas of possibilities, fresh discoveries of those wonderful powers and facts of nature which man to all time will never exhaust. The Mechanical Section of the British Association has done good work in this direction in the past, and we may look forward with confidence to our younger brethren to maintain these traditions in the future.

COMPANIES' MEETINGS AND REPORTS.

BABCOCK AND WILCOX, LIMITED.

The fifth ordinary general meeting of this Company was held on Friday last at the Cannon-street Hotel, E.C., Mr. Andrew Stewart, chairman of the Company, presiding.

The **Chairman** moved the adoption of the report and accounts, a summary of which has been already given in our columns. During the financial year from July 1, 1895, till June 30, 1896, the Company had been able to pay (1) an interim dividend for the half-year ended December 31, 1895, at the rate of 6 per cent. on the preference shares, and a dividend of 5 per cent. on the ordinary shares, amounting to £10,000. The Board now proposed to pay for the half-year ended June 30, 1896, a dividend at the rate of 6 per cent. on the preference shares, and a dividend of 10 per cent. on the ordinary shares, amounting in all to £17,000, making 15 per cent. on the ordinary shares for the year. They had placed to the reserve fund the sum of £25,000, and carried forward a balance to next year of £5,276. 14s. 3d. The arrangement between the Singer Company and the Babcock and Wilcox Company had come to an end in a friendly and agreeable way, and the Board had elected Mr. W. H. Inslee as a director on the Company, to fill the vacancy existing on the Board.

Sir William Arrol seconded the motion, which was carried, and the retiring directors and officers were re-elected.

GREAT HORSELESS CARRIAGE COMPANY, LIMITED.

The statutory general meeting of this Company was held last Friday at the Institute of Chartered Accountants, Moorgate-place, E.C., the Earl of Winchilsea (the chairman of the Company) presiding.

In the course of a long speech the **Chairman** said that the number of applications for motor carriages that had been received had reached a total of 4,000, and the applications for agencies in different parts of the world reached the very considerable total of 750. That, he thought, showed how the wind was blowing and the tide setting. Later on, referring to the motor to be employed, the Chairman said: "I think that one of the greatest boons we could confer on the travelling public would be if we could arrange something which would take the place of horses in our great towns. The choice of agencies which we have is between electricity, steam, and oil. For the present, at least, the use of electricity will probably be confined to those towns where it is possible to obtain supplies of it at a moderate price. That, of course, is the case to a great extent in London, where the electric supply companies are always very willing to supply electricity in the daytime at a more moderate price than they are at night, when there is a great demand on their plant for electric lighting purposes. With regard to oil and petroleum, I think they will probably be most used in rural districts." Lastly, the Company intended to thoroughly test all their vehicles before turning them on the market.

Mr. H. J. Lawson also spoke, and the proceedings ended with the usual vote of thanks.

SIR W. G. ARMSTRONG AND CO., LIMITED.

The annual report and balance-sheet for the year ending June 30 last has been issued. The report shows that, after deducting depreciation, and adding the balance from last year, as per the terms of the agreement, there remains a profit of £358,689. 12s. 3d. upon the year's operations. The directors propose the payment of a dividend of 2s 3d. per share on the ordinary shares, and 4 per cent. per annum on the preference shares of the Company (less income tax), of which 6d. per share and 2 per cent. respectively have already been paid as interim dividend. This leaves 1s. 9d. per share on the ordinary shares, and 2 per cent. on the preference shares now payable, and a balance of £5,709. 0s. 1d. to be carried to next year's account. In accordance with the articles of association, the following directors retire from office—viz., Lord Armstrong, Sir Andrew Noble, Admiral Albini, Mr. Cruddas, and Colonel Dyer. They are eligible, and offer themselves for re-election.

The report of the auditors, Messrs. Monkhouse, Goddard, and Co., states that the divisible profit, including the undivided balance brought forward from the previous year, amounts to £358,689. 12s. 3d., and, after deducting the interim dividend on the ordinary stock and on the preference shares, there is a balance of profit of £275,901. 0s. 1d. The depreciation written off leases, buildings, machinery, plant, etc., amounts to £90,911. 10s. for the year.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Cloetz (Germany).—Among other construction contracts tenders will be received on September 24 for about 11 miles of telephone line for the Altmark Tramways. Particulars are obtainable for one mark (1s.) from the Baubureau der Altmärkischen Kleinbahn, Cloetze.

Berlin.—The construction of an iron bridge at Gitschiner-und-Skalitzer-street in connection with the electric tramway is open for tender. Application is to the Königl. Regierungs und Baurathes Bureau, Markgrafenstrasse 94, Berlin, and the date is September 28.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Paris.—Tenders will be received on October 1, at the Department of Posts and Telegraphs, rue de Grenelle 103, Paris, for about 575 tons of copper wire and a quantity of copper and porcelain telegraphic stores. Application for permission to tender must be made to the Under Secretary of State immediately, so as to be received before September 20.

Odessa.—The Municipal Authorities have decided to offer for tender the electric lighting of part of the suburbs and the new prison. No date is given, and application must be made to the Municipal Delegation at Odessa, but certain particulars can be obtained at the Ministry of Commerce (bureau de renseignements commerciaux), Paris, rue de Varenne 80.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Brussels.—Tenders will be received on October 21, at the Bourse Brussels, for installing the electric light at the Arlon Railway

Digitized by Google

Station, including the offices and works. Particulars are obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Edinburgh.—The Lord Provost, Magistrates, and Council are prepared to receive tenders for the wiring of the Burgh Assessments Office, High-street. Specification, forms of tender, and plans of the building can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, on deposit of two guineas, which deposit will be returned on receipt of a bona fide tender. Tenders must be sent to the town clerk, Mr. Thomas Hunter, City Chambers, Edinburgh, not later than Tuesday, September 22.

Hull.—Pending the decision of the Town Council as to the leasing of the tramways or the working of them by the Corporation, tenders are invited for a license to temporarily work and use the tramways for one year from October 15, 1896, upon the terms and conditions embodied in the draft of an agreement, which can be obtained by application to Mr. R. Hill Dawe, town clerk, Town Hall, Hull. Tenders, stating the amount of rent offered, must be delivered at the Town Clerk's Office, by 10 a.m. on September 21, in sealed envelopes, endorsed "Tender for Temporary Working of Tramways."

Swansea.—The Corporation of Swansea invite tenders for: (*a*) supply and fixing of cables, casings, switch and fuse boards, and all sundry fittings and materials for installing electric light in the Swansea Market, Swansea; (*b*) supply and erection of a temporary generating plant, including gas-engine, generator, and main switchboard, together with the maintenance of the same for a period of 12 months, for the supply of electrical current to the Swansea Market, Swansea. Specifications and forms of tender and any additional information can be obtained from the engineers, Messrs. Kincaid, Waller, and Manville, of 29, Great George-street, London, S.W., on payment of £3 3s. for each specification, and same will be returned when a bona fide tender is received by the Corporation. The plan of the market can also be seen at the offices of the Engineers, or at the Guildhall, Swansea. Sealed tenders to be sent to Mr. Jno. Thomas, town clerk, endorsed "Tender for Electric Lighting Installation, Swansea Market," or "Tender for Temporary Plant for Electric Light Installation, Swansea Market," as the case may be, at or before 4 p.m. on 24th inst.

Morley.—The Electric Lighting Committee of the borough of Morley are prepared to receive tenders for the supply and erection of the following plant. (The whole bound up in one specification; price £2. 2s., returnable on receipt of a bona fide tender): Section A - Boiler-house plant: Lancashire boilers and fittings, feed pump, etc. Section B—Engine-house plant: steam alternators and exciters, motor alternator, accumulators, steam and exhaust pipes, valves, etc. Section C—switchboard and instruments. Section D—overhead crane. Section E—underground work: cables and stoneware culverts. Section F—transformers and switchboards. Section G—arc lamps, posts, and accessories. Section H—meters. Tenderers are at liberty to tender for any section, but not for part of a section. The ground plans of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after Wednesday, September 16, on payment of £2. 2s. for each copy, which sum will be refunded on the return of the specification, filled up with a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to the town clerk, Mr. R. Borrough Hopkins, at the Town Hall, Morley (Yorks), and be delivered on or before Wednesday, October 14.

RESULTS OF TENDERS.

Coventry.—The City Council have accepted the tender of Messrs. W. Coates and Son, at £575, for the fitting up of an installation of the electric light at the gasworks.

Blackpool.—The tender of Mr. Simpson, Hapton, has been accepted for the electric light installation at the Primitive Methodist chapel. Mr. J. B. Thornley, Darwen and Blackpool, is the architect.

Harrogate.—The Town Council have accepted the Edison and Swan United Electric Lighting Company's tender for supplying fittings for the new baths, as under: No. 1, £297. 17s.; No. 2 (alternative), £275. 15s. 5d.

Bristol.—The Electrical Committee have received the following tenders for the additions to the central station, including piling for the foundations:

E. Walters	£23 561	0	0
J. Davis	19,930	0	0
J. Perkins	19 600	0	0
J. Durnford and Son	19,370	0	0
W. Cowlin and Son	18,940	0	0
G. H. Wilkins	18 898	0	0
A. Krauss	18,850	0	0
Wilkins and Gosling	18 557	0	0
C. A. Hayes	18,251	0	0
J. Perrott	17,750	0	0
R. Wilkins and Sons	17 471	0	0
F. Martin	16,725	12	4

It was agreed to accept the tender of Mr. F. Martin, of St. George.

Bath.—The Electric Lighting Committee have adopted Mr. Hammond's report in reference to the extension tenders. This, of course, will require to be formally confirmed by the Council. The amounts of the recommended tenders will be found in our "Business Notes."

Glasgow.—The Corporation Electric Lighting Committee have resolved to recommend the acceptance of the following offers for cables: (1) the Callender Cable and Construction Company for (*a*) 1,566 yards of 1in. cable for the sum of £961. 11s., (*b*) 2,722 yards of ½in cable at the rate of £532 per mile and (*c*) four miles of ¼in. cable for the sum of £1,360; (2) offer by the British Insulated Wire Company for 764 yards of ½in cable at the rate of £603 per mile; and (3) offer by the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, for (*a*) one mile of ¼in. indiarubber cable at the rate of £368 per mile, and (*b*) two miles of potential cable at the rate of £108 per mile.

BUSINESS NOTES.

Nyack (New York).—A new electric yacht for Mr. John Jacob Astor has just been launched.

Litherland.—The District Council have decided to fix a telephone at the Council offices.

Worcester.—The new Hope-Jones electric organ in the cathedral has given great satisfaction during the musical festival.

Change of Address.—Holophane, Limited, have removed to their new showrooms and offices at 91, 93, and 95, Queen Victoria-street, London, E.C.

Huddersfield.—The Electric Light Committee report a deficiency of £116 on the half-year to June, as compared with one of £624 last year.

Penzance.—The National Telephone Company intend to establish an exchange in the borough, and have applied to the Town Council for permission to erect poles.

Royal Electric Company of Montreal.—The Bank of Montreal will pay on and after October 1 the coupons then due of the 4½ per cent. debenture loan for £154 000.

Harrow.—The electric light appears to have proved a great success, and the Electric Light and Power Company have reason to be satisfied with the result of their initial installations.

Mumbles.—An offer has been made to the District Council to light the village by electricity, but the offer was deferred. It was made by Mr. Weaver, who is laying down a plant to light his own house.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending September 13 amounted to £1,262, as compared with £1,278 in the corresponding week of the previous year, being a decrease of £16.

Competition.—It is announced that the municipal authorities propose a competition for the lighting and water supply of Cosne, in the Nièvre, France, but whether electric lighting is contemplated is not stated. The date is January 1 next.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending September 11 were £2,388. 8s. 1d., compared with £2,048. 11s. 2d. for the corresponding period of last year, being an increase of £339. 16s. 11d.

Sheffield.—The motor deputation is visiting various towns on the Continent where motor traction is in use, and the *Sheffield Daily Telegraph* reproduces an account of every system which the deputation inspects, so the ratepayers ought to be able to come to a satisfactory decision.

Direct Spanish Telegraph Company.—The Board have decided to pay, in addition to the dividend at the rate of 10 per cent. per annum on the preference shares, an interim dividend at the rate of 4 per cent., free of income tax, on the ordinary shares, both for the half-year ended June 30.

Electrical Trades Union.—Mr. F. Sims, the organising secretary, informs us that he will address a meeting in connection with this trades union at the Club Union Buildings, Clerkenwell-road, on the evening of September 21, and another at the Horse and Groom, Charlton, on September 25.

City and South London Railway.—The returns for the week ended September 13 were £835, compared with £808 for the corresponding period of last year, being an increase of £27. The total receipts for the half-year 1896 were £10,016, compared with £9,316 last year, being an increase of £700.

Gillingham.—The offer of the electric lighting company to light parts of the district free of charge for two months was accepted at the meeting of the District Council on the suggestion of the Survey Committee. Permission was given to the company to collect the rain-water on the Gillingham-road for their use.

St. Austell.—The Highways Committee was instructed, at the last meeting of the Urban District Council, to meet the engineer of the Telephone Company with a view to arranging for the erection of the necessary poles and wires for the contemplated establishment of a telephone exchange in the town.

Windsor.—Good progress is being made with the new central station in Peascod-street for the Windsor Electrical Installation Company. The foundations have been laid of the chimney shaft, which will be 80ft. in height. The erection of the boiler-house, engine-room, and battery-room is also being proceeded with.

Wolverhampton.—At the Town Council meeting the chairman of the Lighting Committee withdrew his motion that application be made to the Local Government Board for their sanction to a loan of £670 for the purpose of sinking a well and providing pumping machinery at the generating station, Commercial-road.

Digitized by Google

Belfast.—The work of erecting the Mater Infirmorum Hospital, Crumlin-road, is proceeding rapidly. The entire establishment will be lighted by electricity (by Messrs. Coates and Son), and advantage will be taken of the current to drive the laundry machinery, to work the hoists, and to cook in the ward kitchens.

Norden (Lancs.).—The question of lighting the road to Red Plumb was discussed at the meeting of the District Council, and it was suggested that the electric light should be used. It was, however, decided to wait till the November meeting of the County Council, when it was thought that probably something might be done for them.

Douglas.—The offices of the Southern Electric Tramway Company, which are situated at a lonely place overlooking the sea, have been broken into, and the safe, containing a considerable amount in gold and cheques, was forced and ransacked. The thieves afterwards took away the safe, weighing 3cwt., and threw it into the sea.

Southend.—At a meeting of the Town Council a letter from Messrs. Alfred Dickinson and Co., of Birmingham, stating that they were prepared, subject to receiving the sanction and support of the Council, to construct electric railways in the borough, was referred to the Land and Parliamentary Committee for consideration and report.

Morecambe.—The District Council have resolved that £26,000 be borrowed upon security of the general district rate for the purpose of defraying the expense of purchasing the plant and machinery of the Morecambe Electric Light and Power Company, Limited, according to the terms of the agreement between the Council and the company.

Ramsbottom.—The gas company recently offered their undertaking for sale to the District Council if the Council would give a price that would secure the shareholders a maximum dividend in perpetuity, but the offer was declined, and it was suggested that the Council should undertake the electric lighting forthwith, and become competitors to the gas company.

Edinburgh.—The estimates of expenditure for the ensuing year have been passed. The estimates of the Electric Lighting Committee were increased by £500, and the treasurer (Mr. McCrae) stated that the increase on the capital expenditure for electric lighting was almost £4,000, and, in fact, they would be paying this year for that account about ⅛d. per pound.

Stewart Electrical Syndicate, Limited.—This Company has been started, with a capital of £1,200, to manufacture, sell, and supply electric arc lamps, electric incandescent lamps, and electrical apparatus generally, and to carry on the business of suppliers of electricity, electricians, electrical and mechanical engineers, metal founders, etc. Registered office, 16, Paternoster-row, E.C.

Balmoral.—It is understood that arrangements are to be completed forthwith whereby it will be possible for the Court of Balmoral to be in direct telephonic communication with Whitehall and the metropolitan palaces. The new Government trunk cable between London and Aberdeen will be utilised, and all that is now required is a loop wire of low resistance from Aberdeen up Deeside.

Alderley Edge.—At the Urban District Council meeting the Clerk read a letter from the Board of Trade stating that they were prepared to consider the transfer of the provisional order when they were satisfied of the financial position of the transferee. It was resolved to forward to the Board of Trade a copy of the prospectus of the company and pointing the names of substantial gentlemen.

Bootle.—When the proceedings of the Watch Committee came up for confirmation at the Town Council meeting, Mr. Hall asked how soon the deputation which had the matter of electric lighting in hand would be able to place their report before the Council. The Mayor said the report would come before the next meeting of the Watch Committee, and would be submitted to the meeting of the Council next month.

Whitehaven.—The borough electrical engineer is preparing a report on the proposed extension of the cables to Kells. The application by the committee of the working-men's reading-room, in Duke-street, for a supply of electric current was again considered, and the engineer was instructed to report as to the probability of other customers likely to take current on the line of the proposed new main.

Ayr.—About 2,400 yards of cable have been laid in Racecourse-road and district since August 10, an average of over 100 yards per day, at approximately half the cost asked by the contractor, including the extra cost of tarring and laying the boards over the cable. It is doubtful whether the Town Council will be able to supply current to Belleisle before the races commence in that district, but every effort is being made.

Fulham.—The Electric Lighting Committee of the Vestry have considered the report of Mr. F. H Medhurst as to the advisability of the installation of electric light in the parish and the erection of a dust destructor in connection. At the outset the committee passed a resolution agreeing to apply for a provisional order under the Electric Lighting Act. This was all the business done, and no conclusion was come to in regard to Mr. Medhurst's report.

Monmouth.—The Mayor, in reply to several enquiries at the Town Council meeting, stated that as he knew the Council would be anxious to know what prospects they had of commencing the electric lighting and drainage schemes, he had written to the engineers asking them when they would be prepared to advertise for tenders, but so far he had not received a reply. The Council, he might add, would have nothing to do with it till the tenders were sent in to them.

Bristol.—At the meeting of the Electrical Committee the town clerk reported that the Local Government Board had sanctioned the raising of £75,000 on loan, repayable in 25 years. It was agreed to accept the tender of Mr. Martin, of St. George, for additions to the central station, including piling for the foundations, at £16,725. 12s. 4d. The engineer reported that the fourth large engine and alternator had been received, and were being fixed.

Levenshulme. — The Urban District Council at their last meeting adopted the minutes of the General Purposes Committee, which contained a communication from the South Manchester Electric Supply Company, announcing their intention to apply to the Board of Trade for a provisional order to supply electricity for lighting and other purposes in the district. Mr. Tunaley gave notice that at the first meeting of the Council, held next month, he would move that the Council apply to the Board of Trade for a provisional order to supply the district with electricity.

Yarmouth.—At the Town Council meeting the borough surveyor reported that since the last meeting of the Council applications had been received from two customers for 32 lamps, the total number of customers now being 186 for 9,052 lamps. He also submitted a table showing the hours of consumption at which the electric light would be used in places of worship in the town, where the officials had applied for a reduction in price. The matter was considered, and upon the recommendation of the committee the Council resolved not to make any reduction in the price at present.

Coventry.—The Local Government Board have sanctioned the borrowing by the Corporation of £13,000 for electric lighting purposes, the money to be repaid in not more than 20 years. At a meeting of the Electric Light Committee it was reported that 4,148 lamps were now connected, and that present applications for further lights would bring the total up to 5,060. There are now, as a matter of fact, more lamps connected than the smaller plant is capable of supplying. This has necessitated the use of the 200-h.p. engine, whereas hitherto the 100-h.p. has sufficed for local requirements.

Morley.—The Town Council confirmed at their last meeting the minutes of the Electric Lighting Committee, which stated that the committee had instructed Mr. Hammond to purchase necessary materials and lay the pipes or culverts in Queen street from the Bottoms to Fountain street. Specifications submitted by Mr. Hammond for the laying of mains in Queen-street were approved, and he was instructed to advertise for tenders for the carrying out of the work. The committee did not offer any objection to Mr. Hammond availing himself of Mr. Sykes's assistance in the erection of the buildings, but he (Mr. Hammond) must take all the responsibility.

Dover.—At the meeting of the Town Council a letter was read from the district manager of the National Telephone Company stating that they could not make any alteration in their charges to the Corporation, which were at present very low. They were at present engaged in making extensive alterations in the system, incurring considerable outlay, with a view to bringing the service up to date and improving it in every respect. They asked that the Council would give them the permission to place down certain poles in connection with these improvements, a request first made last June. It was decided to obtain a return showing the cost of the Corporation's instruments per year.

Pole-Finding Papers.—As a result of an incidental reference to some specimens of pole-finding papers "made in Germany" which we made in speaking of Mr. Avery's catalogue, that gentleman has sent us some specimens of pole-finding paper of his manufacture, with a request to try them on a continuous-current circuit with a pressure above two volts. This we have done, with the result that might be expected. What is more to the purpose, however, is that Mr. Avery's paper does not give the misleading results that were obtained from the German ones referred to. The fault of the latter was, not that they would not indicate "poles," but that they would find poles where they should not have done.

Cardiff.—At the meeting of the Electrical Committee of the Corporation the electrical engineer submitted three schemes for extending the electric light mains to Canton: (1) extending the electric light mains up Leckwith-road, Cowbridge-road, and Cathedral-road to a point 200 yards south of Sneyd-street, £1,600; (2) tapping a connection in Tudor-road and carrying the pipes up Clare street and Lower Cathedral-road and then New Cathedral-road to the same point, £640; (3) to join on the main at Castle-street and over Canton Bridge to the same point, about £600. On the motion of Mr. Illtyd Thomas scheme No. 1 was adopted, and it was resolved to apply to the Local Government Board for power to borrow the amount of £1,600.

Legal.—In the Vacation Court on Wednesday the case of Everitt *v.* the National Telephone Company, Limited, came before Mr. Justice Chitty. This was a motion for an order to restrain the erection of telephone poles, and counsel on both sides agreed to the continuation for a week of an injunction granted a few days before by his lordship in chambers. In the case of the Callender Bitumen Telegraph and Waterproof Company, Limited, *v.* the National Telephone Company, Limited, in which the plaintiffs moved for an order to restrain defendants from interference with the telephonic apparatus, it was mentioned that an interim injunction had been granted that day, and that the parties had therefore agreed that the motion should stand over until the second motion day at the next sittings, the defendants meanwhile giving an undertaking in the terms of the interim order.

Fareham.—In compliance with a request by Mr. Cobbett, the Urban Council agreed at their last meeting to lay the electric wires to Redlands. Mr. Abraham protested against the delays of

Digitized by Google

the Local Government Board in settling the advance of the money needed for the purchase of the electric light wires, and said that the town seemed to be going to sleep over the matter. That night however, they had before them the question of drawing a cheque for £220 on account of loan and interest, and he would himself write to the Local Government Board on the matter. Mr. Appleby considered that it was time the officials should understand that the business of the country could not be allowed to stand still on account of holidays. On the recommendation of Mr. Manville, the Board's official adviser, it was agreed that a feed-pump for the electric works should be purchased for £9.

Armagh.—At the meeting of the County Asylum Board the report of Mr. J. Greenhill, engineer, with reference to the installation of the electric light plant and the completion of the proposed improvements in the asylum buildings was read. Mr. Greenhill stated that he had examined the tenders, three of which had been selected for the consideration of the Board. The tender of Messrs. Cooney and Swann, Belfast, was as follows: installation of electric light, including dynamo, armature, and storage battery, £985; compound engine, with 140lb. steam pressure, £313; two boilers for 100lb. pressure, £760; two feed pumps, £84—total, £2,142. The amount in the tender of Messrs. Cox Walker, of Darlington, was £1,766, and that of Messrs. Twigg and Chester, London, £1,961. After a lengthy discussion it was decided to hold a special meeting of the Board to further consider the tenders.

Southport.—A scheme is being projected for the construction of an electric tramway from Southport to Lytham, across the Ribble. The plans have been prepared by Mr. Stewart Speddy, of Hampton-road, Southport. It is proposed to build a two-line tramway on wooden piles and ironwork across the Salters' Bank. The distance to Lytham is about six or eight miles. The line would begin near the Marine-parade at Southport and end in the centre of Lytham. It is also proposed to construct a 30ft. carriageway, in addition to side walks. In order not to interfere with the navigation of the Ribble, it is proposed to have a bridge across the channel, which will be raised at the approach of a vessel. Except in mid-channel, the water is very low, and at neap tides the banks are not at all covered. In addition to the tramway, handsome erections are to be built at each end. These will consist of theatres, pavilions, ballrooms, etc.

Cheltenham.—The Town Council have adopted the minutes of the Street and Highway Committee, which we published last week, and which related to the proposed electric tramway. The minutes of the Electric Light Committee were also confirmed. Alderman Norman explained and produced plans for the lighting in the Promenade by lamps suspended at a good height over the roadway. On the occasion of his last report they had something under 100 customers and 5,500 lamps connected; but they now had 117 customers, 18 waiting connection, 8,050 lamps connected and 1,150 to be connected. He added that on the previous Saturday night they had the largest output from the works in their experience, the record being 319 units, or 25 per cent. more than on any previous occasion. Mr. Dimmer mentioned that the penny-in-the-slot apparatus for the supply of electric light was likely to be a great success.

Glasgow.—In view of the proposals for the adoption of electric traction on the tramways, the *Glasgow Herald* has published a special article designed to reassure its readers on the subject of possible dangers from electrolysis. The writer confesses a preference for a cable system, but points out that the mischiefs that have arisen in America have been simply the result of slovenly or cheap construction. Under the Board of Trade regulations they could not occur. Moreover, a complete metallic circuit might be adopted either with a conduit system or, if the inhabitants of Glasgow see no objection to overhead wires, with a double-trolley wire and two trolley poles, as is done in Cincinnati. This, however, would be more expensive and is unnecessary if the assurances of electrical experts can convince people that underground pipes are quite safe with the single-trolley wire system under the Board of Trade rules.

Halstead.—At a meeting of the Urban District Council Messrs. Crompton and Co., of Chelmsford, reported that their Mr. Jenkinson had visited Halstead, and interviewed some of the principal residents and explained to them the approximate cost of installing the electric light in the different premises, and the probable cost of using electricity for lighting, power, cooking, and heating purposes. The results of the interviews were very satisfactory, and there appeared to be a promise of something like 500 lights being taken up as soon as the supply was ready, and this, with the Council's street-lighting, would be, in the opinion of the firm, a sufficient load for a beginning, and would justify the Council in proceeding with the scheme. They gathered also that there was a possibility of customers taking current for power purposes in the daytime. The prospects generally appeared better than they had expected. The matter was referred to the committee.

Bath.—The Electric Lighting Committee have met to consider Mr. Robert Hammond's report on the tenders recently received for the extension of the electricity works about to be acquired by the Corporation. Mr. Hammond's recommendations were as follows: Boiler-house plant (Babcock boilers), Electric Construction Company, £2,462; engine-house plant (flywheel alternators), Electric Construction Company, £8,364; underground works, Callender's Cable and Construction Company (cables), £7,985, Electric Construction Company (converters), £470; overhead travelling crane, Stothert and Pitt, £350—£19,631. With regard to the arc lamps and posts, the tenders varied from £2 224 to £3,545, and Mr. Hammod recommended that each tenderer should erect a sample lamp at Bath, which, working for two months, would give the committee an opportunity of deciding for themselves which maker should secure the preference. It was unanimously decided to adopt Mr. Hammond's report in its entirety for recommendation to the Council.

Fleetwood.—Among the minutes which came up at the last meeting of the Urban District Council for confirmation were those of the Highway and Market Committee, which contained the following report: "That the committee in charge of the Fleetwood Electric Lighting Order, 1890, be authorised to confer with the promoters of the Blackpool and Fleetwood Tramroads during their negotiations in connection with the proposed transfer of the said order and to obtain details of the proposed quantity of pillars which will be required for the streets named in tramway No. 3 in order that complete designs and estimates for such pillars may be submitted to the Council at an early date." The special committee *re* electric lighting order recommended that the clerk be authorised to arrange for an interview between the members of that committee and Dr. Hopkinson, C.E., Manchester, with reference to the supply of electrical energy in the district, as per powers contained in the Blackpool and Fleetwood Tramroads Act, 1896. The minutes have been approved.

The Central London Railway.—The *Daily Mail* has lately been devoting some space to the affairs of this railway. In an interview with the secretary a few days ago, a representative of that paper elicited the following facts: "There are two tunnels, one for each train, and the risk of collision is thus practically entirely removed. Sometimes the one tunnel is on the top of the other, but it does not alter the locomotion at all. The line is being constructed on the switchback system. On leaving the station it takes a sufficient dip to give the train impetus enough to reach the next station. It is calculated that by this method the only motor power required will be in starting the train from the station, thus securing a great saving of expense, though, of course, the power is always there if there should not be sufficient impetus to have the desired effect. There is to be duplicate machinery at the generating station, to avoid the delay attendant on a breakdown. This will be the most expensive line ever built, the cost being estimated at £500,000 per mile, making a total of considerably over £3,000,000 on the whole length of 6½ miles."

Chelsea.—We extract the following from the surveyor's annual report to the Vestry: "The number of houses in Chelsea lighted by electricity for the last three years was as follows:

	1893-4.	1894-5.	1895-6.
Chelsea Electricity Supply Company ...	500 ...	598 ...	777
London Electric Supply Corporation ...	6 ...	9(?) ..	—

The Chelsea Electricity Supply Company, as now extended, have an area of supply throughout the whole of the home district of Chelsea by adding to their district the whole of the parish west of Beaufort-street. The London Electric Supply Corporation have not carried out any further extensions during the past year. I have from time to time examined the records kept by the Chelsea Electricity Supply Company, and find that they still maintain a constant pressure, and the voltmeter fixed in my office generally stands at 100 volts. As the London Electric Supply Corporation do not appear to keep a separate record for the Chelsea circuit, I have not examined their records. The upper hall of the town hall has now been fitted up with electric light."

Eccles.—The letters to the Town Council from the Local Government Board, Mr. Clirehugh, and Edmundson, Limited, on the subject of the electric lighting of the borough have been referred for discussion to the Council in committee. Mr. Clirehugh's letter asked whether the Council will now be prepared to transfer the power conferred on them by the electric lighting order to a private company in return for the out-of-pocket expenses incurred in procuring the same, and also whether in the event of his clients acquiring the powers, the Council would be prepared to grant them the concession for public lighting on similar lines to those suggested in the original scheme. It was stated that the terms on which Mr. Clirehugh's clients would be prepared to take over the electric lighting powers would include some such conditions as were agreed upon with the Altrincham District Council—namely, that the Council would be able to repurchase the order and acquire the installation on terms. Messrs. Edmundson offered to take over and carry out the provisional order upon terms to be arranged, which they stated would be favourable to Eccles.

Appointments Vacant.—The Huddersfield Electric Lighting Committee invite applications for the situation of working mechanical engineer in the electric supply station. The duties will be to keep the existing machinery in repair, connect up additional machinery, and to act generally under the instructions of the borough electrical engineer. Salary £2. 10s. per week. Applications, on foolscap paper, stating age, experience, and accompanied by copies of not more than three recent testimonials (which will not be returned), must be sent to Mr. F. C. Lloyd, town clerk, Town Hall, Huddersfield, by 21st inst., endorsed "Working Mechanical Engineer."—The London School Board require for the training ship "Shaftesbury," off Grays, a stoker mechanic, having a practical knowledge of electric lighting apparatus and steam-boilers, also capable of doing general repairs to pumps, cooking, and other apparatus. Commencing salary £50 a year (which may be increased by £2 10s. a year to £65 a year) with uniform, board, lodging, washing, and medical attendance. Applications, in candidates' own handwriting, on forms to be obtained from the School Board Offices, accompanied by copies of not more than three testimonials, must state age and previous experience, be marked outside "Stoker Mechanic," and be received by the

Digitized by Google

Clerk of the Managers, School Board Offices, Victoria-embankment, London, W.C., by 12 noon on 22nd inst.

Electric Omnibuses.—A meeting of the London Electric Omnibus Company was held yesterday at Winchester House for the purpose of allowing a statement to be made to the proprietors by the directors as to the position and prospects of the company. There was a large attendance. The Chairman explained first of all the history of the motorcar, and quoted a House of Commons report on the subject which was published 65 years ago, and which showed that our legislators 65 years ago were very up-to-date in their opinions. He pointed out that electricity itself was quite in its infancy, for the first House of Commons report was issued as recently as 1879. The first real start in road-locomotive legislation was due to Mr. Shaw-Lefevre, who introduced the Bill into Parliament last year, and every credit is due to Sir David Salomons for his energy in bringing the matter before the public. He claimed for this company that they were the pioneer company, and he was very confident that it would meet with great success. They were beginning in a small way, and as soon as their position was assured, he was informed, they would have no difficulty in getting any amount of money they required to enlarge their undertaking. They had the most improved machinery that it was possible to obtain, and they had had built an omnibus which was the best of its kind the world had ever seen. On the previous night this omnibus was inspected by a few gentlemen at the works at Whitehall.

York.—At the meeting of the City Council Mr. Alderman Agar, chairman of the Streets and Buildings Committee, in answer to Lambert, denied that the committee had any wish to hang up the electric lighting question till after the November elections. The committee were doing what the Council wished them to do. They had applied to Prof. Kennedy to supply them with a specification. They had just lately gone over the specification and made some amendments, and tenders would be advertised for shortly. In answer to Mr. Alderman Rymer, who asked if the committee had advertised for tenders for the electric light or only intended to do so, Mr. Alderman Agar replied that the specification was in Prof Kennedy's hands, and he expected the advertisements would be issued shortly. Mr. Alderman Rymer said that he had asked his question in reference to the electric light because he believed that many of the members did not know that the committee had been given power to advertise for tenders before again coming before the Council. A little while ago he moved a resolution to the effect that no steps be taken to get tenders until the number of citizens willing to take the electric light had been ascertained. That resolution was not passed, and he now moved that the question of advertising for tenders be deferred until the citizens had had an opportunity of expressing an opinion on the electric light at the November elections. Mr. Oakley seconded. The Town Clerk advised the Lord Mayor that the resolution was out of order, and his lordship so ruled.

Bedford.—The following report of the Electric Lighting Committee was adopted at the meeting of the Town Council without discussion: "The committee have to report that the applications for additional lamps for private lighting continue to be satisfactory. Such applications represent equivalent to about 1,000 additional 8-c.p. lamps which will all be connected before the commencement of the winter months. In reference to the application for private lighting in St. Michael's-road the committee regret that owing to pressure of business they will be unable to supply the light at the present time, but they hope to take this district in hand at an early date. The committee have had under consideration the necessity of the appointment of an assistant engineer. They have received an application for the office from Mr. Hansom, who is at present employed at the Hampstead electric light works. The committee recommend that Mr. Hansom be appointed assistant to the engineer at a salary of £135 per annum. The committee have received a request from the postmaster that a lamp be placed so as to light the letter-boxes at the post office, High-street. The committee recommend that the request be acceded to. Applications have been received for the electric light for private purposes from certain residents in Lurke street and The Crescent. These streets are not included in the scheme for this year's expenditure, but the applications represent such a number of lamps as will repay the expenditure, and the committee recommend that they be empowered to proceed with the work forthwith. The engineer has been instructed to procure the additional 4in. iron pipes required for De Parys Avenue and the Embankment."

Birkenhead.—The Finance Committee reported at the Town Council meeting that they had considered the subject of the supply of electricity in the borough. It was expected that the work of laying wires and erecting electric generating stations would be completed by the middle of the month, when the illuminant would be available for consumers in the central districts of the town, where at present mains have only been laid. It had been arranged to introduce the light as soon as possible into the town hall. The standard pressure of energy in the distributing mains had been fixed at 230 volts, and consumers would be charged according to the actual quantity of energy supplied after the rate of 6d. for every unit. The minutes also included a resolution to the effect that on the termination of his present engagement, Mr. Shoolbred be appointed consulting engineer of the electrical works during the pleasure of the Council, Mr. Shoolbred undertaking to visit the works when necessary on payment of £1 for every day on which he attended. Alderman Deakin, in moving the adoption of the minutes, stated that the Corporation originally obtained power to borrow £20,000. The expenditure up to the present was £1,576 for land, and £14,440 for works and plant, making a total of about £16,000. There were various other commitments of the Corporation that would probably bring the total expenditure to something over £21,000. The expenditure, therefore, would exceed the estimate, but he hoped the excess would not be abnormal. With regard to the installation in the town hall, an expenditure of £1,500 had been sanctioned, and the expense under this head would not exceed, perhaps not reach, £1,200. On the completion of the works they would be run by the contractor for a month, and at the end of that time would be formally taken over by the Corporation.

Catalogues.—We have received from Mr. G. Braulik, of 217, Upper Thames-street, E.C., his catalogue of electrical supplies. The volume is really six catalogues bound together, each one of these relating to separate departments. Each of these has its own index, but there is no general index or list of sections, so that until one becomes familiar with the book, which is by no means a small one, it may occasionally be somewhat of a hunt to find the precise article wanted. The general principle of arrangement appears to be to take the lightest work first. Thus we begin with bells, fittings, toys, telephones, medical electric instruments, and so on to cables, dynamos, gas-engines, and the heavier matters of electric lighting. Mr. Braulik is the sole agent for Koerting and Mathiessen, and therefore one of the specialities of the catalogue is the arc lamp of that firm.—Considerations of time made it necessary to keep very short the notice of the catalogue issued by the Newton Electrical Works at Taunton. A further reference may be permitted to the diagrams and full instructions that are given for fixing and working motors. This takes up space which might have been devoted to mere advertisement of the goods of the firm, but if it results in the motors receiving fair and intelligent treatment when left in the hands of men not specially skilled in their use, it will be for the benefit of everyone, not excluding the issuers of the catalogue.—The Dynamo Brush Company, of Finsbury-pavement E.C., send us a catalogue of their new foliated rolled-metal dynamo brushes, incandescent lamps, and electric light carbons.—We have also received a price-list from the "D. P." Battery Company, Limited, which gives prices and full particulars of their storage batteries and complete batteries, renewal sections, and accessories. There is a large number of testimonials given, among which we notice the names of Mr. H. de la Rue and Mr. A. A. Campbell Swinton.

Portsmouth.—An important discussion took place at the meeting of the Town Council on the recommendation of the Tramways Committee that the Council should obtain a provisional order, so that electric traction might be introduced into the borough. Alderman Ellis, in moving the adoption of the report, pointed out that the actual cost of purchase, of reconstructing, of all the electrical gear and machinery, including cables, columns, and everything to complete the business, would not amount to more than from £110,000 to £120,000. Supposing they borrowed the money at 2½ per cent. the annual payment by them would be £6,513, but the company would pay them £7,280 a year, leaving a profit to the Corporation of £767. Supposing they could not borrow the money at less than 2¾ there would still be a net profit of £580 per annum. With the profit on the production of the current, and taking into consideration the present loss of energy they would save by working a 24 hours' load instead of 12 hours', there would be a total profit of nearly £5,000. Councillor Beale seconded without comment. Mr. Gieve moved the following amendment: "That the Tramway Committee be instructed to bring up a full report of the whole question of tramways, such report to be considered at a special meeting of this Council." He believed everybody in that chamber who had had an opportunity of seeing electric traction would agree that it was the traction of the future. The question arose, however, whether it was desirable to proceed with the application for a provisional order, or first thoroughly thrash out the various schemes of electric traction. He had been informed that if the resolution was passed, and application made immediately for a provisional order, it would follow that on December 23 next the Council would have to file a provisional agreement with the Board of Trade. He asked whether the Council thought three months was a sufficient time to thoroughly thrash out the facts and the circumstances that would have to be enquired into in connection with the question. Mr. Kimber seconded the amendment. He was not against buying the tramways, but against buying them without proper investigation. The Council had the power to acquire the tramways in sections, commencing in July next, and ending in 1902. If the company used electricity, and the Corporation were willing to serve them, the company must take the current from the Corporation. After further discussion Alderman Ellis withdrew the report.

Altrincham.—A special meeting of the Urban Council has been held to receive a deputation from the electric tramway company for the purpose of the deputation explaining their scheme and obtaining the assistance and sanction of the Council to the undertaking. The clerk read the communication of the syndicate proposing to lay the tramway from Stretford to near Peel Causeway. The Chairman said it was necessary for the syndicate to get the consent of the Council before going to Parliament for sanction of their scheme. Mr. Andrews, who said he represented a London syndicate who were prepared to invest £500,000 of money in the proposed tramway scheme, explained that they proposed to lay a double line of rail from Stretford through Sale and Altrincham, to Grange-lane, Bowdon, to be worked by the central pole electric system, the wire to be from 18ft. to 22ft. high, so as to allow the highest load of hay to pass under. In answer to questions, Mr. Andrews said they proposed to act as common carriers, and as

Digitized by Google

such to convey farm produce, etc., to Manchester Market in the night, and the carriage would convey 60 passengers each, for which they would charge short penny stages, say to Sale for 2d. The present was only part of a scheme to be continued from Stretford to Chorlton-cum-Hardy, Withington, Didsbury, Heaton, Mersey, Stockport, Heaton Norris, etc., so as to allow of people travelling to any of these townships without going into Manchester. In answer to Mr. Vernon, he said they would be able to supply electricity for lighting purposes at 4d. or probably 3d. per Board of Trade unit, because instead of using the engines 16 hours a day to supply electricity to the consumers as at present for about four hours' consumption, the same use of the engines would produce for the 16 hours' consumption. They proposed to put a 32-c.p. lamp on each pole, and so light the streets along which they ran, but these were all questions of detail that could be dealt with more fully when the scheme was worked out. At the present all they asked was an assurance from the Council that the scheme would receive their sympathetic consideration, when they would be prepared to go on with the necessary expense to lay the scheme in legal form before them, as if such consent were withheld they would proceed no further. The syndicate would be prepared to lease the lines from the Council if they laid them down, or at a time to be fixed they would sell to the Council. The chairman (Mr. Newton) thanked Mr. Andrew for his lucid explanation of the scheme, and said the Council would give it their best consideration and communicate the result.

Brighton.—An official examination of the Brighton and Rottingdean Electric Seashore Railway was held on behalf of the Board of Trade on Saturday by Major Marindin (representing the Railway Department) and Major Cardew (representing the Electric Department). The result was of a most satisfactory character. It was low tide when the sea-going car, as it is called, started from the jetty at Brighton, there being on board Messrs. J. J. Clarke and R. J. Pope (directors of the company), Magnus Volk and St. George Moore (joint engineers), F. J. C. May (borough engineer), and J. K. Nye (solicitor of the company) Major Marindin walked in front of the car the whole of the way to Rottingdean. The car was put to some severe tests. Various obstructions were put on the rails, such as masses of timber and concrete, heaps of flint and chalk, large iron sleepers, and so on, but the car simply brushed them all aside and passed along so smoothly that a pail of water which had been placed on the back of one of the "bogies" or wheel coverings, was not upset nor was any of the water spilled. There was a large crowd of people at Rottingdean to witness the arrival of the car. Major Marindin got on board, and the car was "backed" for about a mile and brought to a standstill. Here it was allowed to stay until the tide had risen. The journey back was at length started upon, when the rails were well covered with water, the depth of which for the last half mile was over 20ft. When the jetty at Brighton was reached it was raining in torrents, but in spite of this about a thousand people had assembled to witness the return of the car. Major Cardew was then picked up, and another start for Rottingdean was made forthwith. The car again behaved in a most satisfactory manner. At Rottingdean an inspection was made of the machinery department. As it had been arranged that the car should stay at Rottingdean for the Sunday so that the residents there might have an opportunity of inspecting it, the party then "disembarked," and returned in cabs to Brighton. The inspectors expressed themselves as perfectly satisfied in every way with the new railway. There are still a few finishing touches to be put here and there, and they stated that when this had been done the certificate would be granted. The inspection was made under circumstances well calculated to severely test the safety of this novel mode of travelling, there being an equinoctial tide with a rough breeze. It is understood that the car will journey at a speed of about 5½ miles an hour at high tide, and from six to seven miles an hour when the tide is out. The engines which supply the motive power are at Rottingdean, and are of 120 h.p. Mr. Volk informs us that the railway will be opened about the end of the month, but that the car runs occasionally now.

Dundee.—At the meeting of the County Road Board of Forfarshire, Mr. A. W. Myles, the clerk, submitted a draft of the annual report to the County Council, which was agreed to. This report stated that the Board had had under consideration the remit from the last meeting of the County Council with reference to the transfer of the trunk wires from the National Telephone Company to the Post Office. In connection with this matter they had now got formal intimation from the Telephone Company terminating their agreement with the County Council as at December 23 next. Under the present arrangement, the county had been accustomed to receive from the National Telephone Company 6d. for each of 1,140 poles by way of wayleave, the sum received having been divided among the various districts according to the number of poles in each district. The county had also had an arrangement by which it had paid the company £7. 10s. for each of 12 connections with certain of the county officials' offices and police stations. As a result of the Government having taken over the inter-town trunk wires, the Telephone Company had given notice that the Post Office had now had transferred to it 860 of the poles, and that the wayleave in respect of these would cease to be paid as at December 23, 1896. After that date therefore, the county would lose the 6d. wayleave upon each of these poles. Moreover, a tariff charge of 3d. would have to be paid by the County Council to the Post Office for every county message passed over the trunk lines. On the other hand, the Telephone Company would continue to pay 6d. of wayleave upon the remaining 280 poles, and proposed to charge £7. 10s. as before for each connection. As the law stood, the Post Office could not make any payment for wayleave, and had no power to make any arrangement reducing the tariff below 3d. per message. It followed that in any arrangement with the Post Office more satisfactory to the county the general law would require to be altered. Other counties were therefore equally interested with Forfarshire. The Board had memorialised the Postmaster-General on the subject, representing that so far as the public work of Forfarshire was concerned the telephone was largely and mainly used in the police service through connections with the company's wires in the various police stations; that police stations were exclusively used in connection with the service of the Government, being on this ground exempted from taxation, both Imperial and local; that, having this fact in view, and the desirability of continuing the use of the telephone in the police service as recommended by her Majesty's Inspector of Police for Scotland, messages on police business over the trunk wires should be exempted from the ordinary tariff rates; and craving his Grace to take the premises into consideration with the view of having the matter referred to remedied at the first opportunity. A reply had since been received from the Postmaster-General, in which his Grace the Duke of Norfolk expressed regret that it was not in his power to exempt police messages from the ordinary tariff rates

Ashton.—The following minutes of the Electric Lighting Committee were adopted at the meeting of the Town Council: "The resolution of the Market, Lighting, etc., Committee, with respect to the laying of mains for street-lighting purposes was adopted, and the list of streets and roads recommended to be handed to Mr. Clirehugh and embraced in his scheme. The town clerk forwarded copy of correspondence with the engineer to the Oldham, Ashton, etc., Tramways Company, and it was ordered that the same be entered on the minutes. The town clerk wrote: 'Referring to your letter of April 16 last, I beg to inform you that at a recent meeting the Electric Lighting Committee of the Ashton Corporation were unanimously of opinion that the Corporation should undertake to supply your company with electric power; and I was instructed to let you know that the committee fully approved of the suggestion to this effect contained in your letter; and to request you to place yourself in communication with Mr. S. V. Clirehugh, of Temple-chambers, Brazennose-street, Manchester, electrical engineer to the Corporation, with a view of devising some scheme by which the proposed supply of power may be arranged.' Mr. Stephen Sellon replied for the company that he was in communication with Mr. Clirehugh on the subject, and he had great hopes that they would be able to come to some arrangement. Mr. Clirehugh attended the meeting and presented and read his second report. In report No. 2 Mr. Clirehugh says: 'As instructed by the committee, I have been in communication with the engineer of the British Electric Traction (Pioneer) Company, Limited, who have obtained powers to construct the electric tramway between Ashton and Oldham, and have, in company with him and Mr. Garcke (the managing director), visited Hamburg for the purpose of ascertaining the methods of working the tramways in conjunction with the electric light undertaking. I find in that city the lighting company charge the tramway company 1·2d. per unit. The lighting company charge consumers of electricity for lighting purposes 10d. The fuel burnt in the generating station is brought from Cardiff, and costs 18s. per ton. The lighting company have supplied and laid the whole of the underground feeders for the traction company free of cost, and maintain the same in good condition. The average annual consumption of the tramway company is 3,000,000 units. The Ashton Tramway Company will guarantee to take a minimum supply per annum from the Corporation of 350,000 units. It would be necessary for the Corporation to provide the following plant to supply this demand: two 200-kilowatt dynamos; two 330-i.h.p steam-engines (only one of these would be run, the second being held in reserve in the event of a breakdown); the necessary switchboard and instruments; and one Lancashire boiler (30ft. by 7ft). The cost of this would, I estimate, not exceed £7,500, including the proper proportion of buildings, etc. I recommend the price to be charged the tramway company be 1½d. per unit. This equals a minimum revenue per annum of £2,200 which is equivalent to £25 per horse-power per annum for a day of 18 hours. Mr. Clirehugh makes the following estimate of cost: oil, waste, etc., £220 per annum; wages, etc., £550; repairs, etc., £190; rents, etc. £320; salaries, etc., £260—total, £1,540. Since my previous report I have gone more carefully into the question of the calorific value of the refuse, and find that considerable diversity of opinion exists regarding the amount of heat obtainable. Everybody is, however, agreed as to the minimum value, which may be expressed as follows: 1lb. of refuse, which evaporates 1lb. of water. In many cases better results are obtained, even as high as 2lb. of water evaporated per pound of refuse I have, however, in my calculations taken the minimum. Fourteen thousand tons of refuse are to be destroyed per annum. This equals, approximately, 38 tons per day. The type of engine I propose will require 20lb. of water (maximum) per horse-power per hour; 38 tons = 85 120lb., which, divided by 20, gives 3,756 horse-power hours per day, which, 18 hours a day, gives 207 h.p. I consider that a reasonable estimate of the number of lamps of 8 c.p. likely to be required in the immediate future is 10,000 Bolton, at the end of its first year, has a similar number. Oldham, at the end of its second year, has 12,000. These towns, although larger in population, have not the same scope, in my opinion, for electric lighting. Having regard, also, to the fact that public lighting is contemplated, it must be borne in mind that each arc lamp is equivalent to 20 8-c.p. incandescent lamps. It must be remembered that experience has proved that only two thirds of the maximum number of lamps connected to the mains are alight at one time. Two-thirds of 10,000 is 6,666, which is equivalent to 200 kilowatts.

Digitized by Google

I propose, therefore, to supply two engines and dynamos, each capable of supplying 200 kilowatts, one being retained a stand-by, and one set of 50 kilowatts for supplying the day load, etc., and for driving the pumps and other power required in the works. The question of boilers and destructors I propose to make the subject of another report. There are approximately five miles of streets in which mains are to be laid.' "

PROVISIONAL PATENTS, 1896.

SEPTEMBER 7.

19729. Improvements in electric traction. Charles Herbert Gadsby, 102, Park-road, Loughborough.

19757. Improvements relating to the connection of constant-current dynamos to electric lamp circuits. William Robert Lake, 45, Southampton-buildings, Chancery-lane, London. (Charles Newbold Black, United States.) (Complete specification.)

19767. Improved methods of and means for controlling electric motors. Reginald Belfield, 322 High Holborn, London. (The Westinghouse Electric and Manufacturing Company, United States.)

NOTES.

Fatal Accident.—We regret to learn that Mr. Wm. Ford, a young electrician in the employ of the City of London Electric Light Company, was accidentally drowned at Lewes on Wednesday.

Electro-Harmonic Society.—We may remind our readers that the smoking concert in connection with this society takes place to-night (Friday) in the banquet-room of St. James's Hall Restaurant, Regent-street, at eight o'clock.

The Goldsmiths' Institute.—The laboratory appliances at New Cross have been improved and increased ready for the winter session, and it is announced that a special course of mathematics for electrical engineering students will be started in November if there are enough entries.

Light Railways.—It has been stated that all applications to the Light Railway Commissioners for orders authorising light railways must be made in November or May. For this year only, however, the application may be made during December, but such application must contain all the information necessary to show that the rules as to notice and advertising the application have been complied with.

A Theatre Panic.—At Rome last Friday, at the Constanzi Theatre, as the performance was approaching its end, the fusing of an electric light wire set fire to the hangings of a box in the fourth tier. There was a certain amount of panic among the audience. Some people fainted, others screamed, but the orchestra played the Italian national anthem. Nobody seems to have been hurt, and though everyone tried to quit the theatre as quickly as possible, the fire was out long before the people.

Obituary.—All interested in physical science will hear with regret of the death of Mr. Hippolyte Fizeau, which has taken place at age of 77. Mr. Fizeau will, of course, be remembered for his classical researches on the measurement of the velocity of light, not to mention his other work in physical optics and allied branches of science.—On Wednesday the death was announced at Ockbrook, Derby, of Mr. John Warwick, for over twenty-five years telegraph superintendent of the Midland Railway, and the inventor and patentee of the block system. Mr. Warwick retired from the Midland Company's service in 1879.

British Association.—Next year's meeting of the British Association is to be in Canada, at Toronto, and at the meeting of the General Committee at Liverpool Sir John Evans was nominated president. The American Association for the Advancement of Science—which is not quite so big an affair as the British—has recently met, and it was proposed there that their next year's meeting should be a purely formal one, the American Association merging itself into the British. This, however, though recommended by the committee, was not agreed to, but the date and place of the American meeting was fixed with a view to going straight on from one meeting to the other. In 1898 the British is to meet at Bristol. There was an application from Glasgow, but the northern city gracefully recognised Bristol's prior claim. The meeting for 1899 is to be held at Dover, concurrently with the meeting of the French Association at Boulogne, as we announced some time ago.

Telegraphy Without Wires.—In the discussion on Prof. J. Chunder Bose's interesting paper at Liverpool, Mr. W. H. Preece referred to the following experiments. Mr. Marconi some time ago approached the Post Office officials with respect to an invention for transmitting signals without wires. The first experiments were carried out on the top of the Post Office, St. Martin's-le-Grand. Mr. Preece could not divulge the full details of the apparatus, but a 10in. induction coil was used with a Lodge originator and a parabolic reflector. The first experiments were so successful that the apparatus was taken to Salisbury Plain, and with assistance from Mr. Kempe further trials were made. With these crude instruments, the first made by the inventor, they succeeded in transmitting signals 1¼ miles. Further experiments will shortly be made, and it may be found that these Herzian waves will eventually be exceedingly useful in certain cases.

Acetylene.—Mr. F. Clowes has been studying the behaviour of mixtures of air with gradually increased proportions of acetylene when brought into contact with flame. The proportion of acetylene was progressively increased from 1 to 82 per cent. The mixture containing 3 per cent. of acetylene was the first which was affected by contact with the flame placed either above or below. A pale-green flame slowly traversed the mixture, showing that it was feebly explosive. As the proportion of acetylene was increased, the rapidity of combustion increased, and even a small volume of the mixture gave decidedly explosive effect. When 22 per cent. of acetylene was present, the explosive combustion of the mixture was attended with a slight separation of unburnt carbon. As the proportion of acetylene was increased the separation of carbon was more marked. The limit of explosibility, as judged by the flame traversing the mixture, was reached when 81 per cent. of acetylene was present.

Advanced Evening Classes.—The councils of King's College and University College, London, have inaugurated a series of advanced courses of lectures and demonstrations of a university type for the benefit of evening students who are unable to attend the day classes which are held at these colleges. The courses will be in every respect similar to the courses held during the day. They will be delivered by the college professors, and the college laboratories will be opened to the evening students as freely as to the day students. In order to make the courses accessible to poorer students the fees will be considerably reduced, the fee for each course of 20 or 30 lectures being £1. 1s. The programme for the present session includes courses on mechanical engineering, on electrical engineering, and on practical chemistry by the professors at University College, and courses on civil engineering, on architecture, on experimental and practical physics, and on pure mathematics by the professors at King's College.

The Transformation of Tramcars.—According to the *Electrical World*, it would appear that electric traction superseded the horse so rapidly in Connecticut that old tramcars became a drug in the market, and when the trolley system was introduced in the various cities in that State the problem as to what should be done with the old cars remained unsolved until some enterprising genius suggested using them for summer cottages, "hunters' camps," lodges, etc. The public readily fell in with the idea, with the result that all the 600 old cars that went into disuse are now being utilised for these purposes. It is stated that all along the Long Island coast, from Watch Hill to Larchmont, the cars may be seen perched up by the shore. To Norwich (Connecticut) is due the idea of arranging four cars in the form of a hollow square and erecting a canvas awning in the square. One of the cars is used as the kitchen, and the others as sleeping-room, dining-room, parlour, etc. One gentleman has five cars on Block Island, which he has placed end to end like a train,

Digitized by Google

The supply of old cars in Connecticut has thus suddenly become exhausted.

Old Weights and New Measures.—The Associated Chambers of Commerce have passed the usual resolution. It is to the effect, "That the Executive Council be requested to use every opportunity of urging upon the Government the compulsory adoption of the metric system of weights and measures." At the British Association they debated the subject, but in the Economics Section. Various ways of stretching or squeezing our old measures to fit the new were discussed. Sir F. Bramwell professed his preference for the old system he can use with such marvellous facility; other people showed that they were incapable of conceiving of "decimals" in any other way than as a degraded and hampered form of proper fractions. Naturally, therefore, they prefer the freedom of the vulgar variety of fraction and convert their decimals for calculation. It is not the only instance of a bad habit acquired at school persisting through life. Of course, the question has been really settled for the present. That which never ought to have been illegalised is to be legalised again, and the matter will then stand over for a time.

Electrical Teaching.—Mr. G. R. Peers, A.I.E.E., of Manchester, has been delivering a public lecture at the Halifax Technical School as a preliminary to a course of lectures to classes which will extend over 30 weeks. There was a fair attendance. The headmaster of the school, Mr. J. Crowther, in introducing Mr. Peers, remarked that in a place like Halifax they ought to benefit considerably by attending those classes. He also informed the audience that electrical engineering was practically in its infancy, and the subject was one that might be easily acquired. The first statement has been heard before once or twice. It is one of those things which, however true when first spoken, gets less true the longer they are repeated. As to the second, it is somewhat new, and if it is the result of personal experience, we can only congratulate Mr. Crowther on the possession of unusual ability. To some of us the path of perfection in electrical engineering seems neither short nor easy—the more one learns the more remains to know. But everybody who attends a class or a lecture is not going to be an electrical engineer—fortunately for the profession. And if only a portion of the public should manage to acquire rather less wild notions on the subject of electricity than generally prevail, they might leaven the rest, to the advantage of everyone.

Calcium Carbide Furnace.—A new form of electric furnace (the Lori patent) for the production of calcium carbide is described in *L'Elettricità*. The furnace is carbon lined, and the anode is a carbon rod coming vertically down through the top of it; the cathode is a horizontal carbon plate, and is therefore normal to the rod. Immediately under the latter the plate is pierced with a hole, which is usually closed with a carbon plug, but this can be withdrawn by a lever, and it is through this hole that the furnace is discharged of the finished product. The furnace is fed from the side through an archimedian screw, and consequently, except when the bottom plug is momentarily withdrawn to discharge it, it would be practically gas-tight. The object of this is to save the carbonic oxide, which is the other product of the reduction of the lime. The carbonic oxide is drawn off through orifices in the top of the furnace, and after being purified is stored in a gasholder. From thence it is led back into a masonry chamber surrounding the furnace and there burned so that the initial temperature of the furnace and feed is raised to as high a point as possible and the amount of heating work to be done by the current diminished. The furnace appears to have been set up at Capua, but there are no details as to its working. If all the carbonic oxide were saved, the amount would be about the same as the quantity of acetylene that can be generated from the carbide manufactured. It might be worth while under certain circumstances to save it for use, say in a gas-engine. A cheaper non-gaseous fuel would do just as well to warm up the furnace. Burned in the ordinary way the heating power of carbonic oxide is not particularly great.

Telephones and Subscribers.—The National Telephone Company is not the only one by any means that has to put up with hard words as to its service. The following statement of the influence of the telephone on the average subscriber is from the New York *Press*. The New York *Electrical Engineer* says it is exaggerated and untrue, but reprints it in full. "The telephone system, as manipulated by the American Bell Telephone Company, is not only an insolent monopoly, but is the greatest unciviliser of the age. The average man who goes to the transmitter to call up a friend or for business becomes a savage. The service in this city is so poor that he is in danger of becoming a devil. If bad language felt as hot as it sounds, our telephone subscribers would have a sure revenge against the company, inasmuch as a few well-chosen words would suffice to fuse the wires and wreck the plant." And so forth with a great deal more which we do not think it worth while to repeat. The end of it is a statement that nearly all of the local profanity is expended upon the telephone, the cable cars, and the gas monopoly. "And of these three, telephone, cable car, and gas, the worst of all is the telephone!" We had always understood that the prompt adoption and general use of the telephone was one of the things the Americans prided themselves on.

The Other Sections.—All that was done in those sections of the British Association which treat of matters coming within the proper province of the *Electrical Engineer* will be dealt with elsewhere than in these notes. But one need not attend always strictly to business, especially in September, and therefore a brief note here may be made on the doings of those other sections in which the physicist and the engineer are as mere laymen. Prof. Gaskell brought out his new theory of the relationship of the vertebrates and invertebrates. It was generally not approved. But before we discussed that we should want to know whether there was any relationship. Science knows nothing of the origin of life. But of the many improbabilities, the suggestion that it originated once only, and that all living things are descended from one original group of "cells," is surely the most improbable. What wants explaining is why the possible origins are so few. But the biologist is otherwise minded in the matter. Mr. F. Darwin discussed the problem of the ascent of sap in trees—a problem of some mechanical difficulty. Prof. Poulton insisted that the earth must be older than she looks. He successfully pitted Prof. Perry against Lord Kelvin's estimate One need not bother about estimates of the life of sun—that is so very speculative. In the end probably the physicists and the evolutionists will have to abate some of the rigidity of their laws and meet each other half-way. As for *Pithecanthropus erectus*, *alias* the "missing link," it would be better if his bones were not so scattered. He was found just where he was expected, but though he had a man-like leg his skull was simply ape-like. So it seems that he took to walking on two legs instead of four before he grew brain and became (more or less) sensible. All sorts of arguments may be started from that. Perhaps it is true—perhaps not. Lastly, in the Economics they discussed "futures" and silver. It is to be hoped that the latter subject may not

Digitized by Google

be resumed next year in America. Fortunately no one has yet proposed to remonetise copper as well as silver. If they did, in the name of the electrical trade we should have to protest.

The Anatomy of a Steam-Engine.—We have received from Messrs. G. Philip and Son, Fleet-street, a volume, with plates, which is entitled a "Model of a Horizontal Steam-Engine." Messrs. Philip have already mapped out the interior organs of the human body, of the horse, of the ox, and of the sheep by a system of superimposed plates, and they now appear to have served the horizontal steam-engine much in the same way. The book is intended for the use of general readers and elementary engineering students, and is translated from the original of Mr. C. Volkert, of Nuremberg. Some of the letterpress, however, at the end of the book, not to mention the geometrical appendix, will prove rather tough work for the general reader who knows nothing of mechanism. Meyer's variable expansion gear is taken as the type of a variable gear. It should be thoroughly understood that the engine is treated purely from an anatomical point of view. Nothing whatever is said as to the correct dimensions of the parts, nor are such matters as variable load, initial pressure, expansion, and cylinder condensation treated of. But without some reference to these it is not possible for the general reader to have much idea of what it is all for, or why "one way of letting the steam in and out of the cylinder is better than another." He must therefore take what is said on expansive working entirely on trust. Every engine is not fitted with Meyer's gear in the same way that every sheep is fitted with the same sort of compound stomach. Nature makes no leaps, but so long as the organ does its work the mechanical engineer may alter its construction in any way he pleases—and he does so. These are inevitable difficulties when a book of this kind goes beyond the simplest and most elementary form of engine. Subject to these limitations the book is a good enough one. The plates are thoroughly well drawn and coloured, while the descriptive part appears to have been carefully done. As in the case of the rest of Messrs. Philip's publications the printing and general turn out are excellent.

Chelsea Polytechnic.—We have received a copy of the prospectus of the day and evening classes at the South-West London Polytechnic Institute in Manresa-road, S.W. The institute was opened last October, and it is stated that already about 1,400 students have used it. The work hitherto has been mainly in the evening, but after September the institute will be opened to day students in mathematics, mechanics, mechanism, architecture and building construction, drawing-office work, the workshops, electrical technology, physics, the physical and electrical laboratories, chemistry, chemical laboratory, and applied art. The hours will be from 10 a.m. to 1 p.m., and from 2 p.m. to 5 p.m., on each working-day except Saturday, when the hours will be from 10 a.m. to 1 p.m. It is intended that students should be able to go through a complete course of electrical engineering, mechanical engineering, architecture, technical chemistry, applied art, and Colonial training in two years, provided the whole day is given to the work. If only a portion of the student's time is available, the classes are so arranged that he may get through a precisely similar course in three, four, or more years, and similar courses are provided in the evening. The objects of the day classes are either to give that preparatory training which will fit students over 15 years of age for practical work in the factory or engineers' shop, or such additional education as pupils may require after leaving school before entering on a higher technical and scientific course of instruction such as is provided at the Central Technical College in Exhibition-road. Looking through the prospectus it will be seen that the electrical engineering and physics department is attended to by Mr. H. Tomlinson, with an assistant professor, three "demonstrators," and one "instructor." In view of the dispute now going on as to the training of chemical experts in this country one naturally turns to the chemistry section. Of course the prospectus can at present only tell us what the institute hopes to do. Anilines and dye-stuffs and the benzine radicle generally get shoved off to the last, as usual. But in practical work "each student will work separately . . . and the work will be suited to the particular investigation" the student is interested in. Obviously the institute will do what it can. But it must be remembered that while we have concerned ourselves with only one or two branches, the Chelsea Polytechnic is going to justify its etymology by giving instruction in ever so many trades—including home dressmaking and vegetarian cookery.

The Theory of Lectures.—It will be remembered that, when Mr. James Swinburne started to deliver four lectures on applied electro-chemistry at the Society of Arts last spring, he said pretty plainly that what he intended to do was to show a series of experiments which could not very well be described in print, and the published lectures would be something altogether different. Mr. Swinburne further made it clear that under the circumstances the less his four lectures were reported the better he would like it. Some papers accepted the intimation, others did not. The *Electrical Engineer* was quite convinced that the author knew best whether he was reportable or not. Mr. Swinburne's theory is that the only conceivable reason for anyone going to a lecture instead of reading a book is in order to see experiments which he could not see elsewhere. For a great many classes of experiment this involves the awkward corollary that the utility of a lecture varies more or less inversely with the number of the attendance. Some experiments suffer a little from being thrown on a lantern-screen and viewed from the back of the gallery. However, we do not on that account intend to quarrel with this theory of the lecture; and it would be still more ungrateful to complain of Mr. Swinburne endeavouring to adjust matters to the theory, especially since it has involved his doing double work, and giving us not only a series of experiments, but a striking discourse also. Now that the latter is being published it must indeed be admitted that it has very little in common with what was said at the Adelphi. One of the troubles of the science-trained man when he is asked to apply his knowledge to practical questions—such, for example, as the determination of the possible dividends to be earned by adopting a new process—is that he finds that he must not only know the theory and practice of his own branch of science, but something also of half a dozen others which have no theoretical connection with it. Consequently, we have the first of Mr. Swinburne's lectures on practical electro-chemistry almost entirely given over to what used to be called political economy. The value of the diffused special knowledge that exists in a district where a particular industry has been carried on for a generation is a matter that is very much overlooked. It obviously has some of the characters of the "unearned increment." The questions of who actually gets the benefit of it and who is ethically entitled to it, and whether in the name of equality you cannot tax it, would form a lovely subject for the wilder school of economists to quarrel about.

Motorcarts.—There has been a race for motor cycles from Paris to Mantes and back, a total distance of about 70 miles. The average speed was 16 miles per hour. The

Digitized by Google

"autocar race" from Paris to Marseilles and back, which should now be in progress, is confined to steam and oil motorcarts. The British Motorcar Club is to be very much to the fore there. Major Tulloch has gone over from the British Government to investigate the working of motor-cars in France, and has been entertained at a dinner given in his honour by the Automobile Club of France. In reply to a speech made by the president of the club (Baron de Zuylen de Nyevelt), Major Tulloch admitted that England was far behind France in respect to automobilism. At this the French naturally applauded. The *Engineer*, which has given much attention to the subject, says, "it seems to be impossible, for the present at all events, to work an engine exploding oil vapour without producing a nuisance." On the whole, our contemporary believes in steam, but enumerates a formidable list of difficulties. The exhaust steam has to be got rid of by an air condenser, which is not easy to work in a small carriage; also there is the difficulty of providing ample starting power. Little is said of electricity as a motive power, not, however, because its probable value is underrated, but "because its use must be highly specialised. An electric dogcart would not meet the wants of a country doctor, simply because he could not obtain the electricity; but there is no reason why electricity might not serve very well in a butcher's cart. The charged accumulators and the joints for delivery might be put into the vehicle together. A morning's round of five or six miles performed, the exhausted batteries could be returned, and a fresh set put into the vehicle with another load of meat, and so on. A gas-engine and dynamo for charging the accumulators would be much less expensive to the butcher than the half-dozen ponies they would replace." Butchers are a courageous and enterprising race, especially in the matter of driving. It may be, therefore, that the innovation in vehicles will come from them. But we confess that, in view of the usual desire to find peril, danger, and dismay in anything novel, we should prefer that the public should make its first acquaintance with the electric cart in the hands of someone a little less dashing than the average butcher boy. Lastly, Mr. Cumming Macdona has written to the *Times*. His idea of a go-ahead place is Budapest, so being there he expected to find motorcarts running there as well as electric trams. Instead of which he found that the city authorities had suppressed them "on account of accidents." But city authorities have been known to do that sort of thing before.

Electric Concentric Cables.—Mr. J. Hetherington has contributed an article to this month's number of *Cassier's Magazine* on high-pressure concentric cables and their accessories. Mr. Hetherington had the supervision of the first concentric cables laid in London in 1890. The English practice as to concentric cables is compared with the Continental, and the importance of being absolutely certain of the water-tightness of the lead casing is insisted on. Mr. Hetherington is naturally an out-and-out advocate of the alternating current under all circumstances. It is just as convenient for near distribution, he says, as the continuous current, and "motors require little consideration in England as yet." Further, he believes that there is an unmistakable trend in English practice in the direction of high pressure and in the employment of concentric cables—lead-covered and generally armoured. As it is impossible to do anything on high-tension cables when the current is on, jointing-in and other operations "are generally done in the small hours of the morning." But "whatever the hour, there is pretty certain to be some consumer on the circuit looking for a burglar or entertaining a birthday party when the current is cut off." As there is a competition in London between high and low tension, "the complaints of consumers receive very respectful attention." The various methods of avoiding this cutting off are referred to, and the convenience of a concentric cable with the outer member at the earth's potential. After a description of the London Electric Supply Corporation's 10,000-volt mains from Deptford to London, Mr. Hetherington in summing-up says: "The cost of concentric cables is about 7 to 8 per cent. greater than two single cables of equal sectional area, both being lead-covered. The armouring generally used is much cheaper than the cast-iron pipes, being about one-fourth to one-sixth of their cost (the difference diminishing with the size of the cable), and it is doubtful if the ability to draw in and out is worth the cost of the pipe. In the writer's opinion the cost of pipes can be more economically sunk in copper at the outset, a 3in. pipe representing, in this respect, about 0·1 and a 4in. pipe about 0·15 square inch sectional area of two conductors. Where armoured cables are used it is very necessary to get in the outside section at the beginning, as the cost of laying mains is enormous in London, and often varies greatly in the different districts and parishes into which London is divided; the writer had 16 different scales of charges to deal with in as many parishes. In this instance the dearest parish for reinstatement cost, per yard run, five times as much as the cheapest, and three times the average of the 16 for similar work, the difference being almost entirely due to the different methods of the surveyors. Where the reinstating is allowed to be done by contractors it can be done at a fair profit for less than half the average vestry charges and to the vestry's satisfaction, so that, although municipal labour is a very fine thing, it is not coincident with economy where a company without voice or control in its direction has to settle the bill. In concluding, the writer may express his belief that the Deptford scheme has demonstrated that current can be generated at high pressure (some of the dynamos can work at 13,000 volts) and directly transmitted from the machines by underground concentric cables with safety and certainty to distant transforming stations, where it can be lowered in pressure to anything that may be necessary. Transformers are now at work reducing from 10,000 to 100 volts at one step."

Commercial Communications. — At the autumn meeting of the Associated Chambers of Commerce at Southampton, the subject of telephonic facilities was yet once more discussed. Mr. Massey, of Hull, moved a resolution expressing the opinion that the utility to the mercantile community of the trunk telephone cables between mercantile centres was very materially decreased owing to the great delay in securing connections, and impressing upon the Government the necessity of promptly increasing or improving the main cable connections. The motion having been seconded, Mr. Rowlett, of Leicester, expressed his woes. He complained that while up to the present he had been able to subscribe to the trunk line communication, he had received notice that after March next he would have to pay for every individual message. Another grievance he had was that the Post Office were charging one penny for every time they "called up" a correspondent who might not be at hand at the moment. This should be remedied without delay. Mr. Zossenheim, of Leeds, said we were the first commercial country in the world, yet we had the least telephonic convenience. And so forth. The motion was carried. There was also a resolution on telegraphic communication. Mr. Firth, of Heckmondwike, moved that a memorial should be presented to the Secretary for the Colonies calling his attention to the slow progress made in carrying out the request of the Ottawa convention

Digitized by Google

for cable communication between the colonies and the mother country, and as to the subsidising of a line of fast steamers between England and Canada. Mr. Plumer seconded this. He pointed out the danger that might arise in time of war through important sections of our cable communication being the property of American owners, and then repeated the tale of how Mr. Jay Gould went into an office in the West Indies and monopolised the wire for two hours every day in the exercise of his power as a large shareholder. The resolution was carried. The result of this has been to produce a contradiction of the tale from Mr. R. T. Brown, the secretary of the West India and Panama Telegraph Company. That gentleman, in a letter to the *Times*, says he is instructed to repeat that "the story is in all essentials false; that the late Mr. Jay Gould was not a shareholder in this company; and that his messages at Trinidad took their turn with the other traffic; and that the only difference between the treatment of his telegrams and those of the public was that the usual courtesy offered by every telegraph and railway company to the directors of associated lines, of not charging for their personal messages or conveyance, was extended to him during his visit to Trinidad. Mr. Gould was a director of the Western Union Telegraph Company of New York, to which enterprise, through one of its controlled extensions, the British and other West Indian colonies granted their concessions for the establishment of the West Indian telegraph system. I may add that the whole international traffic of the West Indies does not occupy the cables in the aggregate two hours a day, while that of Trinidad can be dealt with in a few minutes. The charge of Mr. Jay Gould's being allowed to monopolise the lines is as absurd as it is untrue." The tale is one of a class which, in the intervals of abusing them, the Americans like to tell for the glorification of their millionaires. One must have some romance in life. It really has nothing to do with the question of the desirability of this country being able to depend in all cases on the integrity of its telegraphic communications with outlying parts of the Empire. After all, the question is really one of whether the available cash were best spent that way or in other directions.

Scientific Education.—We fully imagined that "Y's" letter was to finish the correspondence in the *Times* on science and technical teaching, but after a day's remission it began all over again. A German says it is the fault of the private schools, which teach nothing practical. Rather, we should say, of the parent, who is content with what they teach. Next we have a Scotsman. He is pseudonymous, and German at that, but we imagine that his name begins with N. He has studied in his own bonnie Scotland and in Germany also, and has to confess that Germany turns out the better results. Not that the raw material is better. "The first-year German student," says our Scotsman, "does not look a hopeful subject. I should venture to back for general mental fitness any odd dozen of Scotch Bejans against a similarly selected dozen of German 'Füchse.'" Nor is it English athletics. The kneipen and kater and Frühschoppen, not to mention the culture of Gambrinus, may fairly be set off against these. Nor is it the equipment of the schools. "Much of the best work of the past has in Germany been carried out in buildings whose fittings are beneath all criticism. In Prof. Ostwald's laboratory in Leipzig I was set to work in a miserable dark, damp cellar, which was, however, luxurious in the matter of water and gas compared with the rooms on the ground floor. Even some of the British municipal technical schools sneered at by 'Chemical Manufacturer' are better supplied with secondary batteries, etc., than this famous physico-chemical laboratory. In Würzburg I worked in rooms devoid of some of the most elementary conveniences of a chemical laboratory; even the few draught cupboards which existed were frauds." It is the examination system which is in fault. "There, I take it, is one of the great obstacles to our progress. Our laboratories, our professors, and our students are cancelled to inanity by the reaction of our Chinese system of examination on lazy human nature. Change the German system of granting degrees to the British method and I guarantee the bulk of the Berichte of the German chemical society will drop 75 per cent. in a couple of years. I cannot imagine the German student continuing to 'research' after the immediate necessity of it has been taken away. It is not in average student nature, be it British or German." The universities should give their degrees, not for examination results, but for research. There is probably a good deal of truth in this conclusion, but we should get at it by another train of reasoning. Richly endowed as our classics and "arts" faculties are, the work of our best and most advanced classical scholars has been largely inspired in its direction, at any rate, by the influence of German scholars. Sir B. Samuelson and the "Chemical Manufacturer" amplify what they have said before. Prof. Clifford Allbutt defends what no one attacked—namely, the high quality of the scientific teaching provided at Cambridge. There are no chemists because the manufacturer does not want them. There is a "spirit of opposition in almost all manufacturers to any introduction of scientific studies. It is not only that as a body they ignore science or shrink from the trouble of it, but also that they have a positive aversion from it; the intrusion of the scientific spirit makes them fretful and even angry. They believe this spirit to be destructive of the dexterity, smartness, and shrewdness in the affairs of the day to which they believe, and rightly believe, that their own success was due." Like master, like man—only more so. There is the British workman to reckon with. Some of the few firms who would "dare not introduce scientific methods. These methods, where introduced, have been brought in with the greatest caution, and at the risk that foremen first and then the rank and file of workmen would throw down their tools. The men might be beaten, but few employers will face the risk of closing their works; they had rather potter on with things as they are. The British artisan is the most skilful workman in the world, and he knows it; an English or Scotch fitter can turn out work better than any other work in Europe, and his machines, therefore, outlast those of any other country." But he will not turn to new methods until it is too late. "An able engineer, the head of large works in the North of England, told me, not a year ago, that the only way in which he could introduce a new labour-saving appliance was to throw it down in the shop with an indifferent and sceptical air; after it had lain there for some weeks, some foreman would take a fancy to it and bring it forward as an adoption of his own." Lastly, comes a complaint (20 years old) that a manufacturer will not believe that the geometry of a university professor can help him in the setting out of toothed wheels. As he probably believed that geometry and Euclid were one and the same, the poor man is to be excused. Ignorance and unwillingness to admit it we shall have with us always. From the hospitable columns of the *Times* the conflict overflowed into the British Association. Sir Henry Roscoe's views are known, and those of the other eminent men of science that spoke on the subject at Liverpool. Prof. Fitzgerald, however, defended the ideal of the universities—with modifications.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 289.)

61. If the E.M.F. and current in a circuit obey the simple harmonic law, and the angle of lag (Art. 18) is known, then we can at once calculate the power. In order to show how this may be done we shall have to prove the following two auxiliary propositions:

I. *The mean value of the product of two simple harmonic functions which are in phase with each other is equal to half the product of their maxima values.*

Let the two functions be represented by $A_1 \sin pt$ and $A_2 \sin pt$ respectively. At any time t, their product is equal to $A_1 A_2 \sin^2 pt$ (Art. 8). Hence the mean value of this product will be equal to $A_1 A_2$, multiplied by the mean value of $\sin^2 pt$. But the latter quantity we have shown (Art. 57) to be equal to $\frac{1}{2}$. The mean value of the product considered is therefore $\frac{1}{2} A_1 A_2$, which establishes the proposition.

II. *The mean value of the product of two simple harmonic functions which are in quadrature with each other*† *is equal to nothing.*

Let A L C M E (Fig. 49) and R B S D T be two sine functions which are in quadrature, and let the dotted line represent the values of the product of the two functions. Between A and B, and C and D, this product is negative, since the functions are of opposite sign; between B and C, also D and E, the product is positive, since the two functions are of the same sign over these intervals. Consider two points, H and N, which are equidistant from B. From the symmetry of the sine function it follows that H O = N P, and I H = N G. Hence the product of the two sine functions at the point H has precisely the same *numerical* value as at the point K. The same holds for every pair of points equidistant from B. Hence it follows that the positive half-waves of the dotted curve are equal in every respect to the negative half-waves, and, therefore, the mean value of the product considered over any complete number of periods is nothing.

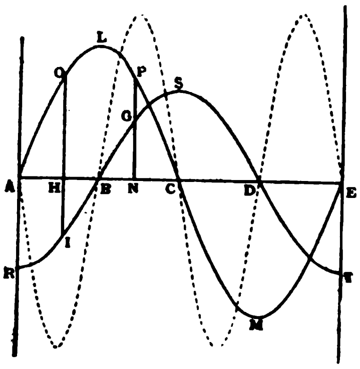

FIG. 49.

We may now apply the above results to the determination of the mean product of two sine functions with any phase difference between them whatever. Let the two functions be represented by the alternating vectors derived from the rotating vectors O A and O B (Fig. 50), the phase difference between which amounts to θ (Art. 18). Let the rotating vector O B be replaced by the two equivalent rotating vectors O C and O D (Art. 18), the first of which coincides in direction with O A, while the second is at right angles to it. This is equivalent to the splitting up of the simple sine wave L M N O P into two simple harmonic components (shown dotted in the figure), which are in quadrature with each other. If the sine function derived from the rotating vector O A be represented by O A sin pt (Art. 16), then that derived from O B will be represented by O B sin $(pt - \theta)$. But, referring to the figure, we see that

$$OB \sin (pt - \theta) = OC \sin pt + OD \sin \left(pt - \frac{\pi}{2}\right).$$

The problem is to find the mean value of

$$OA \sin pt \times OB \sin (pt - \theta),$$

i.e., of

$$OA \sin pt \left\{ OC \sin pt + OD \sin \left(pt - \frac{\pi}{2}\right) \right\},$$

or, $OA \sin pt \times OC \sin pt + OA \sin pt \times OD \sin \left(pt - \frac{\pi}{2}\right)$.

Applying proposition I. proved above, we find that the mean value of the first term is $\frac{1}{2}$ O A × O C. The mean value of the second term is, by proposition II., nothing. Hence the mean value of the product of the two functions is $\frac{1}{2}$ O A × O C. But O C = O B cos θ (Art. 12), so that the mean value of the product is $\frac{1}{2}$ O A × O B × cos θ. If, now, we suppose that the sine function derived from O A represents the E.M.F. in a circuit, and that derived from O B the current, then we have the following proposition:

If the E.M.F. and current in a circuit follow the simple harmonic law, then the power is equal to half the product of the maxima values of these quantities, multiplied by the cosine of the angle of lag.

62. The component of the current which is in quadrature with the E.M.F. is, as we have seen (Art. 61, Prop. II.), a current which does no work in the circuit; it transfers part of the energy developed by the source of alternating E.M.F. to the circuit, storing it up there in the form of a magnetic field. This storage of energy goes on so long as the component considered is increasing; when it reaches its maximum value, the storage ceases; and during the next

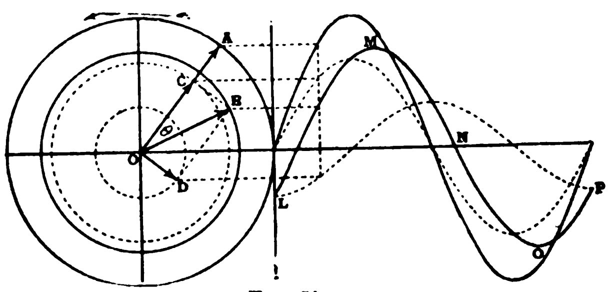

FIG. 50.

quarter-wave, when the component is decreasing, the energy is discharged from the circuit and returned to the source of alternating E.M.F. If in Fig. 49 the curve A L C M E represent the E.M.F. wave, and R B S D T that component of the current wave which is in quadrature with the E.M.F., then the dotted curve will be the power curve corresponding to that component, and the resultant power is nothing. For this reason, the component of the current which is in quadrature with the E.M.F. is sometimes termed the *idle* or *wattless* current.

The other component of the current, being in phase with the E.M.F., is always of the same sign as the E.M.F., hence the power due to this component is always positive. For this reason the component is sometimes referred to as the *load* current.

In Fig. 51 is shown the power curve corresponding to the E.M.F. and current curves of Fig. 50. This power curve may be analysed into two components: the one (shown dotted) corresponding to the *wattless* current, and consisting of equal positive and negative half-waves; the other (shown chain-dotted) corresponding to the *load* current, and containing positive half-waves only.

It is hardly necessary to draw the student's attention to the fact that a *wattless* current could not exist *by itself.* In order that this might be the case, it would be necessary to make the angle of lag $\frac{\pi}{2}$, a condition which would require the resistance of the circuit to be equal to nothing (Arts. 38 and 2).

63. If E and I denote the maxima values of the E.M.F. and current, which we suppose to obey the simple harmonic law, and if θ stand for the angle of lag, then, as we have

* Based on a series of evening lectures delivered at the University College, Liverpool.

† Two simple harmonic functions are said to be *in quadrature* with each other when the phase difference between them amounts to $\frac{\pi}{2}$ (one right angle).

Digitized by Google

seen (Art. 61), the power is $\frac{1}{2}$ E I cos θ. This cosine of the angle of lag is a quantity which, under different guise, we have already had occasion to consider when dealing with the more general case in which the E.M.F. and current may vary according to any law (Art. 59). For $\frac{1}{2}$ E I $= \frac{E}{\sqrt{2}} \times \frac{I}{\sqrt{2}}$, and by the results established in Art. 57 $\frac{E}{\sqrt{2}}$ and $\frac{I}{\sqrt{2}}$ are the R.M.S. values of the E.M.F. and current respectively. Hence $\frac{1}{2}$ E I gives us the *apparent watts* in the circuit—*i.e.*, the product of the volts and amperes (Art. 59); and cos θ is the multiplier which converts the apparent into the true watts. We thus see that cos θ is simply the *power factor* (Art. 59) for the circuit considered.

64. The presence of inductance in a circuit has the effect of displacing the current relatively to the E.M.F., thus giving rise to an idle component of the current, and lowering the power factor. But, like many other things, inductance is not an unmitigated evil, and in some cases is made to serve very useful and important purposes. We shall work out a numerical example to show how in some cases considerable economy may be effected by pressing inductance into service.

Let a group of 10 incandescent lamps, each of which takes one ampere at 60 volts, be required to be run off alternate-current mains at 100 volts, with a periodicity of

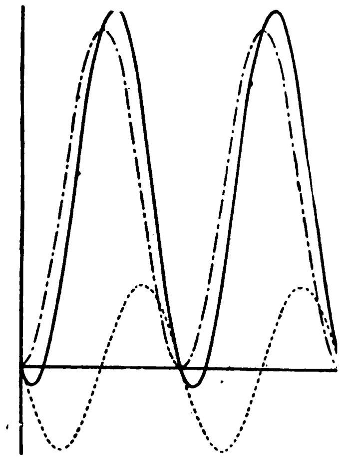

FIG. 51.

100 ⁀‿ per second, the E.M.F. following the simple sine law. The lamps being connected in parallel, their joint resistance will be six ohms. The problem, then, is to reduce the P.D. from 100 to 60. This might be done by using a simple resistance of four ohms. The objection, however, to this method (which is the only one available in the case of continuous currents) is that the resistance would absorb fully $4 \times 10^2 = 400$ watts, the lamps themselves requiring only $60 \times 10 = 600$ watts. Obviously, such a method would be very wasteful. There is, however, another method which is available with an alternating-current supply. This consists in using a *choking coil* to reduce the P.D. A *choking coil* is a coil (generally provided with an iron core) whose inductance is great compared with its resistance, and which is used in the same way in alternate-current working as a resistance is in the case of continuous currents. As an approximation, we shall suppose that the resistance of our choking coil is negligibly small, and that its inductance is L. The impedance of the coil will be equal (approximately) to the reactance p L (Art. 38). The resistance of the lamps being six ohms, the impedance of the whole circuit A B (Fig. 52) across the mains will be $\sqrt{6^2 + p^2 L^2}$. Now the current required is 10 amperes, and the P.D. is 100. Hence, we must have

$$10 = \frac{100}{\sqrt{36 + p^2 L^2}},$$

from which we find $pL = 8$, so that $L = \frac{8}{2\pi \times 100}$ $= \cdot 0127$ henry. A coil having this inductance will therefore reduce the P.D. so that the lamps will work at 60 volts.

65. The obvious advantage of a choking coil over a simple resistance lies in the fact that the former absorbs very little power; if we could entirely get rid of resistance* the coil would absorb absolutely no power. As it is, the small amount of power absorbed is easily determined by multiplying the square of the current by the resistance of the coil. In practice, choking coils are largely used with arc lamps for parallel working.

66. There is one point in connection with the problem we have just considered to which it may be well to draw the student's attention. If a non-inductive resistance is used to reduce the P.D., then the P.D. at the terminals of this resistance will be $4 \times 10 = 40$ volts, and the P.D. across the mains is the sum of the P.D.'s across the lamps and resistance respectively. But if a choking coil is used, then, calling x the unknown P.D. at the terminals of the choking coil, and remembering that

P.D. = current × impedance (Art. 38, equation 23),

we have

$$x = 10 \times L\,p = 10 \times 8 = 80 \text{ volts.}$$

The P.D. at the terminals of the choking coil is therefore not 40, as the student might at first sight have supposed, but 80. The sum, therefore, of the P.D.'s across the lamps and choking coil respectively does *not* give the P.D. across the mains. The reason for this, at first sight, somewhat puzzling fact lies in the phase difference between the two quantities. In the case where a simple resistance is used the two P.D.'s are both in phase with the current, but the P.D. of the choking coil is in quadrature with the current, so that in the second case the P.D. across the mains is represented by the hypotenuse of a right-angled triangle having its two sides equal to the P.D.'s across the choking coil and lamps respectively, as shown in Fig. 52.

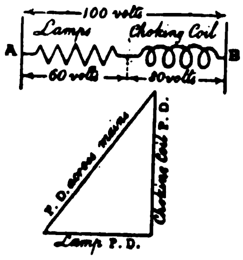

FIG. 52.

In this connection the student would do well to refer back to Arts. 37 and 38.

(*To be continued.*)

ELECTRIC GLOW LAMP TESTS.†

BY WILLIAM HENRY PREECE, C.B., F.R.S., ETC.

So much has been written on glow lamps, and so ably did Prof. Ayrton and Mr. Medley treat the subject in a paper read before the Physical Society on December 14, 1894, and on January 25, 1895, that it is now somewhat difficult to discuss any new question of commercial and scientific interest. However, as I have been investigating the quality of various glow lamps since the Edison-Swan patents collapsed, in order to establish a fair and reasonable specification for the Post Office requirements, and to find, if possible, an expeditious as well as reliable way of testing the efficiency and durability of lamps submitted in competition and delivery, I thought the results obtained would not be unwelcome to the members of the British Association.

My experiments were conducted on the following lines: (1) To find the efficiency and life of 100 and 105 volt 16-c.p. and 8-c.p. lamps in a trial of 2,000 hours' duration when kept alight continuously (night and day) at a constant voltage and the filaments at an approximately uniform temperature. (2) To ascertain the efficiency and life of lamps when similarly maintained at constant potential, but lighted for several consecutive hours daily, as in an ordinary installation. (3 and 4) Similar to (1) and (2), except that the duration of trial was limited to 1,000 hours. (5) To find the mean breaking voltage of filaments by gradually increasing the voltage for each lamp at about the same

* And *hysteresis* in the iron core, if one is used.

† Paper read before the British Association at Liverpool.

rate. (6) To see what the effect would be on similar filaments after being raised to three-fourths of their mean breaking voltage, as found by (5).

As several distinct series of experiments have been made by me since the end of 1894 it would perhaps be advisable to deal with each group separately. Between the months of February, 1894, and April, 1895, the lamps named in the preceding table were tried.

The whole of the following tests were carried out with a continuous current. All the electrical measurements of voltage and current were made with a Hartmann and Braun voltmeter, in conjunction with an Ayrton and Perry twisted strip amperemeter, and each instrument was frequently verified against a standard d'Arsonval galvanometer. A few secondary cells were used to regulate the dynamo potential on the 105-volt circuit,

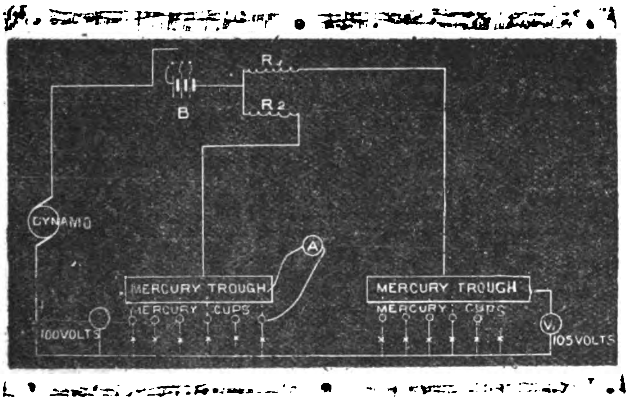

Fig. 1.

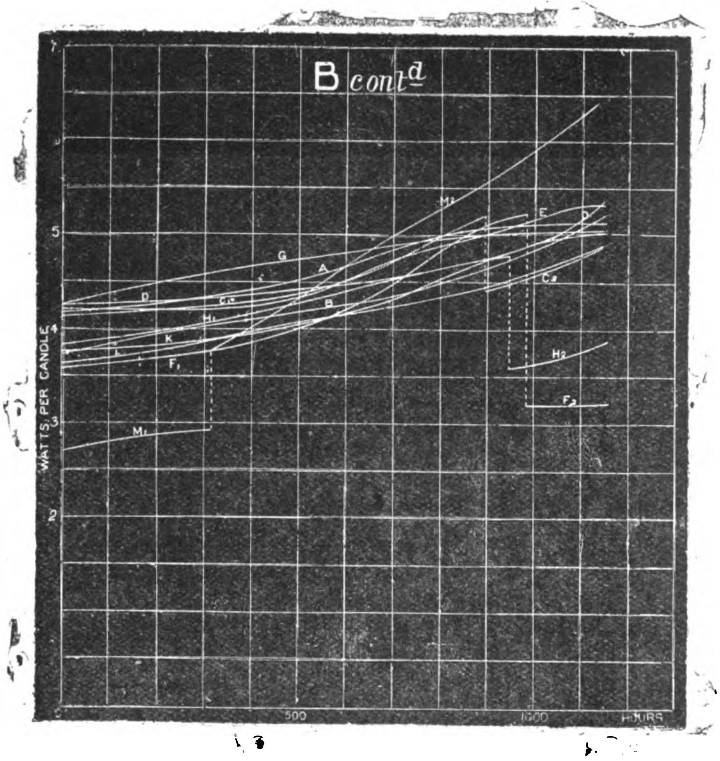
and adjustable resistances were employed to maintain the required potential at the ends of the respective lamps (Fig. 1).

For the continuous lighting experiments each lamp was fitted in a proper lampholder, attached to which was a short length of flexible twin conductor, and until the lamps were wanted for measurement they hung on hooks outside the photometer in positions marked to correspond with the lamps. To ascertain the candle-power of any one of the lamps, it was passed through a small door into the photometer space, and suspended from a clip on a carriage which could be moved over a graduated photometer bar. The illuminating power of the lamp was balanced against Messrs. Sugg and Co.'s standard candles on Rumford's shadow principle, and to ensure the greatest possible accuracy the mean value of the following three observations were recorded as the result: (1) through green glass; (2) through red glass; and (3) without any vitreous medium while the two lights were carefully shaded from the observer's eyes.



B.—Efficiency Curves, Corresponding to Curves A.

Two lamps out of 24 of each make were selected at random—one 16 c.p. and one 8 c.p., of 105 and 100 volts. The potential marked on the lamps was kept constant, and the current and candle-power were carefully measured once in every 24 hours. If a lamp collapsed within the prearranged 2,000 hours' trial, its life was noted, and another lamp substituted without delay. From the results obtained the following curves, A, B, C, and D, of "candle-power and life" and "watts per candle and life" have been prepared for 16-c.p. and 8-c.p. lamps comprised in Groups A and B. In addition to the above curves the summaries for Groups A and B show, at the end of 1,000 hours candle-power and efficiency, percentage drop in candle-power, and the "comparative efficiency" calculated on the assumption that an Edison-Swan 105-volt nominal 16-c.p. lamp, taking 3·75 watts per candle, is 100 per cent. efficiency. From the corresponding curves the behaviour of any one lamp at intervals of 100 hours can easily be obtained if required.

Edison-Swan. 105 v. (I.) ...	16·9	39·0	61·0	69·5	65·25	First 105-volt lamp tested. The second 105-volt behaved more like the 100-volt lamp referred to above.
Electrical Co. 105 v. (I.) ...	15·0	65·3	34·7	59·1	46·9	—

The following four lamps started considerably below the stated 16 c.p., and are therefore regarded as of no comparative value :

Bishop's Cluster Co. 105. (I.)	14·0	11·9	—	—	—	—
Laing, Wharton, and Down. 105. (II.)	13·1	22·5	—	—	—	—
Brush Co. 100. (I.)	13·0	7·8	—	—	—	—
Sunbeam Lamp Co. 105. (I.)	12·0	22·6	—	—	—	—

The curves A, B, C, and D seem to indicate four classes of lamps: (1) those that start at about their nominal candle-power at a high efficiency, but very quickly show a decided falling off in candle-power and efficiency, and become practically useless in 400 or 500 hours ; (2) those that start off at about their nominal candle-power, give a useful light for about 1,000 hours, and then burn out ; (3) those that start off like (2), but do not break ; and (4) those that start off with a candle-power below their nominal value, and keep it up fairly steadily for 2,000 hours, or more.

With Class 1 lamps, frequent renewals will evidently be necessary to keep up a satisfactory light on any installation of considerable magnitude, but, as will appear later on, it would seem that my old prediction of a "short life and a merry one" is not to be disregarded. Classes 2 and 3 are apparently the most promising lamps for practical use, while those in Class 4 scarcely admit of fair comparison with the others in that they never reach their nominal candle-power. Throughout the prolonged tests of "continuous lighting," it will be seen from the data supplied that the candle-power of each lamp gradually dropped from the start to finish and the watts per candle rose.

GROUP A.

The lamp below started considerably below the stated 8 c.p., and is therefore regarded as of no comparative value:

Greenhill. 100 v. 8 c.p. (I.)......	6·4	16·4	83·6	59·0	71·3	—

during the first 400 hours. It then gradually rose 10 per cent. (6·18 candles) to the 800th hour, after which the light slowly diminished to the starting luminosity, but the watts per candle were then higher than at the beginning of the trial. Lotz-Abbott lamp, 100 volts, 16 c.p. (No. 2), rose from 13·3 to 14 candles in 400 hours, and then fell continuously. Lotz-Abbott lamp, 100 volts, 8 c.p., began at 7 and increased to 7·9 candles in 500 hours, and then dropped gradually. In 1,400 hours the candle-power was the same as at the commencement of the test. The watts per candle varied from 5 at the start to 4·71 at the 1,400-hour point. Two other lamps, as made by Stearn and the Crystal Electric Lamp Company, slightly increased in candle-power up to 200 hours, and then slowly diminished.

(To be continued.)

Mexican Patents.—The Mexican Congress has passed a new patent law which will enable patents which have been accidentally forfeited, owing to failure to comply with the stringent conditions of the existing law, to be revived, providing payment of the fees is made and various forms complied with within three months of the promulgation of the new law.

ELECTRICAL BUSINESS IN NORTH SPAIN.

Some little time ago we called attention to a consular report by our consul at Bilbao wherein it was stated that, though a good deal of electrical work had been done and was contemplated in the North of Spain, very little of that work came to English firms.

We have somewhat carefully investigated matters of trade in the North of Spain during a visit to that region. Confining our remarks here almost entirely to electrical business, we may at once say that it is questionable if English firms realise the amount of work that has been done or is under consideration. If they had realised the fact, their travellers and agents would be more in evidence. We found little or no indication of English enterprise, but much of French, German, and Belgian, and even American. At the present time, however, America and all things American are tabooed. Our investigations showed that, as is usual with many English firms, attempts had been made to do business after the fashions which hold here, with no consideration for the methods which govern Spanish action. "You English people are accustomed to say 'yes' or 'no' if you want or do not want a thing. The Spaniard procrastinates, and up to a point maintains he does not want a thing when he wants it all the time. 'No' with him does not always mean 'no,' but means that the old bartering and chaffering spirit is too strong, and that he hopes by this means to run down the price at which the goods are offered." Then, again, in order to obtain business, competitors have undersold us, not, indeed, with goods of equal quality, but with such goods as we could easily supply if it were not that we have a little conscience left, and having asked a price for goods that will really pass muster we do not change our price for other goods of an inferior quality. Insulated wire, for example, can be sold at varying prices; but though all the wire may be sold as insulated wire, that does not guarantee its insulation. Fittings, again, are fittings; they may be cheap and when new catch the eye, but that does not prove them to be serviceable and lasting. The cheap and nasty have caused many troubles in Spain, and among the more far-sighted there seems an inclination to pay some attention in the future to quality as well as to price. A fact not always thought of in ordinary discussion is that "town" may mean quite a different thing to one person than to another. Towns in England are large and populous—in Spain many towns are not so large as our villages, and have the houses scattered over considerable areas. Many of these small towns are already lighted electrically. Travelling through the Pyrenees one is surprised to see the station, the streets, and some of the straggling houses fitted up with the incandescent lamp. The surprise ceases when it becomes known that water power is available, coal almost unknown, and oil the only possible illuminant to compete against electricity. At many of these places electricity was eagerly welcomed, and for such small places is heartily supported.

It was our good fortune to meet with the

Digitized by Google

principals of a firm commencing to take a somewhat active part in matters electrical. This firm is in negotiation with three towns about to introduce electricity. They pointed out that not only was it necessary to get firms of repute to carry out the work, but they must be prepared to send men of experience to supervise the carrying out of the work. In several cases plants have been brought and sold, and badly installed. The latter has caused a good deal of dissatisfaction, and good machinery has brought its maker into disrepute because of this. Once more we must repeat that, so far as we could gather, the day of excessive cheapness is past. No English town would permit for a moment such buildings as constitutes the central station at San Sebastian. No English company or municipality would think of erecting them except as a temporary makeshift. Bilbao is but little better, and, in fact, most of the structures we saw labelled central stations were more of the character of old-fashioned barns than for the protection, preservation, and due maintenance of valuable machinery. We trust, at any rate, that some of our English firms will make enquiries as to the possibilities of work in Spain, and that business may be obtained from such enquiries. In writing upon this subject previously we referred to the question of money. We were assured that money was not wanting, that it would be forthcoming, but that business must be transacted keeping in view Spanish as well as English methods.

CORRESPONDENCE.

Justice needs that both be heard."

WORKHOUSE LIGHTING BY ELECTRICITY.

SIR,—Would you oblige by inviting, through your columns, anyone who could give information as to any workhouse or other similar establishment which has been or is about to be lighted by electricity to communicate with me. My Board is considering the subject, and would much esteem any particulars furnished to them which might be of assistance.—Yours, etc.,

CHAS. TAYLOR, Clerk to the Guardians.

Isle of Thanet Union, Minster, Ramsgate,
Sept. 18, 1896.

CABLES.

SIR,—We have read with interest the letter from Mr. Callender referring to our high-conductivity lock-armoured electric cables. We see that he gives you notice that this is an infringement of certain patents issued to Messrs. Latch and Batchelor as far back as 1884. We may say that these patents refer to matters with which we are not concerned, and they do not affect the novelty of our new electric cable. If Messrs. Callender and Co. consider that they can prevent our manufacturing and selling our armouring, we shall be willing to meet them at the proper time in the Law Courts, where the question can be settled by proper authorities. Meanwhile, we shall continue to advertise, vend, sell, and use our new electric cables, and we desire through your columns to inform our friends that we are perfectly prepared to protect them against any action that Messrs. Callender and Co. or others may think proper to take.

We would also like to thank Mr. Callender for his letter to you, for we very much appreciate his kindness in calling the attention of the trade to our manufactures.—Yours, etc.,

W. T. GLOVER AND CO.

Westminster, S.W., Sept. 21, 1896.

ELECTRICAL DISTURBANCES IN SUBMARINE CABLES.*

BY W. H. PREECE, C.B., F.R.S.

Many interesting problems arise from time to time in the practical applications of electricity which tend to develop, or confirm, theoretical deductions on a scale beyond the dreams of the laboratory experimenter. In no branch has this been more pronounced than in submarine telegraphy. Long-ocean cables contain invariably only a single core.† Multiple cables—that is, cables possessing more than one core—are usually short in length, and are, in consequence, free from those disturbing elements which, existing in long lengths, make such circuits difficult to operate successfully. A *disturbance* is the result of the expenditure of energy in the wrong place. It tends to loss of efficiency. In telegraphy this means mutilation of signals and loss of speed in working. In telephony it means indistinctness of speech, the presence of extraneous and distressing sounds, or the reduction of distances through which speech is practical.

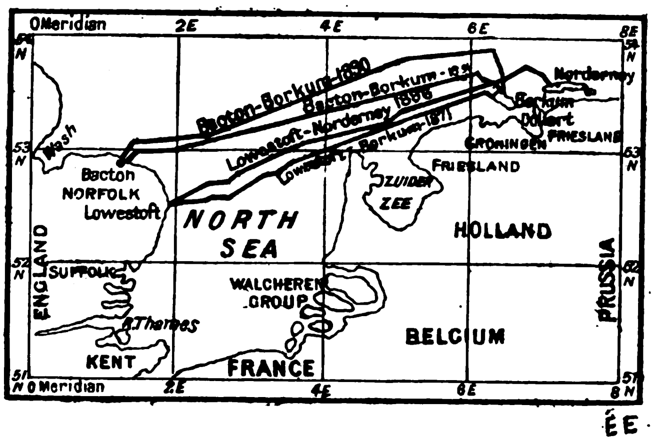

FIG. 1.—Map of Part of North Sea, showing Bacton-Borkum (2), Lowestoft-Norderney and Lowestoft-Borkum Cables.

The longest multiple cables worked by the British Post Office are those connecting the coast of Suffolk and Norfolk with Germany, and these cables have four cores each. The following table gives their lengths and particulars:

Name of cable.	Date laid.	Length in nautical miles.	Capacity in microfds K.	Resistance in ohms. R.	K R.‡	Remarks.
Lowestoft-Norderney	1866	225	73·1	2,710	198,100	No brass tape.
Lowestoft-Borkum	1871	225	66 0	2,666	175,950	Ditto.
Bacton-Borkum	1891	211	63·0	2,380	149,940	Ditto.
Bacton-Borkum	1896	224	84·0	1,510	126,000	Separate brass tape round each core.

The Norderney and other cables in the North Sea having been attacked and punctured by the *Limnoria terebrans*, a small boring mollusc, it was decided to cover the cores of all new cables with brass tape armour, an effective remedy against this depredator. Hitherto brass tape had been used solely for this particular purpose. It was wrapped round the whole of the cores after they were stranded together; but for other reasons which will appear, the second Bacton-Borkum cable, laid this year, had each core separately and independently so protected. These four cables, each with four cores, form 16 circuits, of which 14 are worked as a rule by the Hughes type-printer; but on two circuits the double-current Morse system is employed. In all cases the earth is used as the return. The

* Paper read before the British Association at Liverpool.

† The term *core* is applied to the copper conductor and its insulating sheath or dielectric.

‡ The product K R expresses the law that the time constant of a circuit varies as the product of its active capacity and its ohmic resistance.

Digitized by Google

presence of disturbances from induction was first seriously brought under notice after the laying of the Bacton-Borkum cable in 1891. This cable is one of the ordinary four-core P.O. standard type, without any brass taping, a section of which is shown in Fig. 2. On commencing to work the four wires, it was found that, although we had a perfect cable, with better copper, and guttapercha of lower static capacity than usual, the Hughes working upon the four circuits was very unsatisfactory. Twelve months after its submersion, a series of observations was made upon the three then existing Ango-German cables, when it was made clear that there was still very much more disturbance upon the 1891 Borkum than upon the old cables *viâ* Lowestoft.

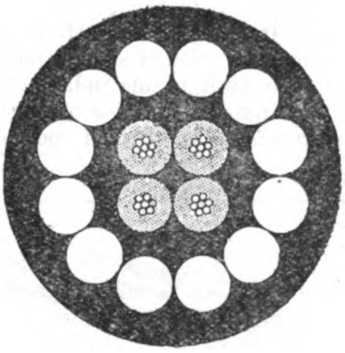

Fig. 2.—Ordinary Four-Core Submarine Cable. Deep-Sea Type. 107lb. Copper, 150lb. G.P. to Scale.

After very careful examination and consideration it was concluded that the difference was due to the better mechanical condition of the new cable, upon which the compound was still practically sound, preventing a complete and continuous soaking with water of the hemp yarn around and between the cores, with the consequent absence of the shielding effect which existed in the older cables, owing to their more thorough saturation. It was consequently assumed that the new cable would improve with age. But this disturbance presented itself in a more serious manner when attempts were made to work *duplex* Hughes, and also when testing the Wheatstone automatic system upon one of the cores. It was found that duplex Hughes was just possible, but owing to the disturbance from the other cores the signals were mutilated so frequently that working was too unreliable for ordinary business. The disturbances from Wheatstone working were still more serious. The Hughes apparatus is worked by short, sharp, intermittent currents, separated from each other by varying intervals of time. These time intervals determine the letter to be printed. The latter maintain the same direction throughout. The former vary with the *voltage* and the latter with the *amperage*.

During the experiments with the Wheatstone system, to which I have referred, it was found that the disturbances on the Hughes circuits, due to automatic sending on another core of the same cable, increased with the rate of working. Thus, with the same voltage—viz., 80—at key speed (30 words per minute), the effect was negligible; automatic (40 words per minute), the effect was distinct; automatic (50 words per minute), the effect was serious; maximum speed of the cable (70 words per minute), the effect was prohibitive. The greatest disturbances were observable when automatic and Hughes were working in opposite directions. The signals on the Hughes were sometimes in advance and sometimes in retard. Hence they were so greatly mutilated that Hughes working was impossible This was due to the *consonance* which occurs in two parallel circuits. When the mutual inductive influence, either electrostatic or electromagnetic, or both, between them, produces in either conductor greatly increased or greatly diminished currents, the one will advance and the other retard the signals so as to render telegraphy impracticable. The brass tape around each core entirely shields the conductors from electrostatic induction. The separate and independent brass taping of the 1896 cable has fully complied with my anticipations. The disturbances upon the cables are reduced to a negligible extent. They are one-sixth of those observed on the 1891 cable. They would entirely disappear if we could remove the electromagnetic effects. The possible rate of working, after several months' submersion, on the new cable is 33 per cent. greater than on the 1891 cable, but this is due chiefly to the reduction of the K R. The improvement in the signals is shown by the two recorded curves (Fig. 3).

The time constant* of the 1891 cable is 0·0513 second, and that of the 1896 0·0450 second, measured by the Hughes instrument, which is a capital chronograph.

Part II.—Telephone Cables.

An important form of multiple cable to consider is that required for telephone working. The cable connecting England and France, forming the Channel section of the London-Paris telephone circuit, has cores of the ordinary type as shown in Fig. 1, using guttapercha as the insulating medium, but with its capacity and resistance reduced to a minimum. It gives two circuits between London and Paris, and works very satisfactorily; but we want to bridge over greater distances, and eventually we hope to reproduce speech even across the Atlantic. The Dover-Calais type would not do for a greater distance than, say, 30 nautical miles. The distance to Belgium is 47 nautical miles, to Holland 108, to Germany 211 nautical miles. These cables had been all tested to see if speech was possible on them, commercially or experimentally. On the cable between Bacton and Borkum, which is 211 miles long, no telephonic signals could be distinguished. On the Holland cable, however, speech was experimentally possible but not practical with the present apparatus. With paper as the dielectric, having half the specific inductive capacity of guttapercha, and with our later experiences of air spaces, cannot we devise a new form of cable that will bridge over these greater distances? We must eliminate all disturbances, and we must reduce capacity and resistance to their lowest limits. The former is simple, for well-insulated, symmetrically-twisted metallic circuits are free from all external disturbances. The latter

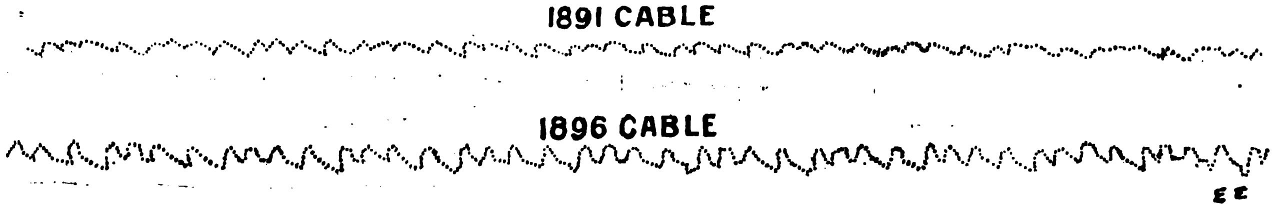

Fig. 3.

The causes of disturbance are induction and leakage. The latter may be ignored, for the insulation of our cables is practically perfect. The induction may be either *electrostatic* or *electromagnetic*. The former is the primary agent in reducing the speed of working in telegraphs, and in deteriorating the clearness of speech in telephones. A part of the energy of the current is absorbed by the capacity of the line, and stored up as a charge producing in discharge retardation and prolongation of signals. Electrostatic induction between core and core is the principal cause of the disturbance between the conductors of multiple cables. Electromagnetic induction also produces serious disturbances on straight parallel circuits with earth return, whether used for telegraphs or telephones, but between the two wires of a metallic circuit it may have a very beneficial influence in telephone working. It is very easy to differentiate the electrostatic from the electromagnetic effects. The former differ in direction at each end of the circuit when discharging.

* The *time constant* here referred to is the time that the current takes to rise to the necessary strength to work a relay in normal adjustment.

Digitized by Google

is more complicated, and is surrounded with great practical difficulties. The problem is to diminish the time constant of a metallic circuit so that it shall approach zero. If there were no time constant, current waves would rise instantly to their working maximum and as rapidly fall to zero. If we could materially diminish the causes of retardation in such cables, speech by telephone would be possible to great distances. This can be done theoretically by neutralising the effect of static capacity by the opposite effect of electromagnetic induction.

The conditions which retard current waves and thus determine the time constants in single conductors embedded in a solid cylindrical dielectric are very different to those which act in double conductors or parallel metallic loops. Lord Kelvin in 1855 dealt with the cases of direct currents and distributed capacity in a complete single circuit. The surface of the conductor in such a cable is one plate and the earth the other plate of a condenser. At every point of the course of the current this capacity must be satisfied. Work is done on the dielectric in establishing an electric field. Lines of electric force are formed through the medium, varying in number with the force exciting them and with the thickness and specific inductive capacity of the dielectric. Energy is stored up. The charge thus held must be neutralised or dissipated. Discharge to earth through each end is the result, and this, with the resistance of the circuit, produces retardation of signals. Neutralisation has been attempted in submarine telegraphy by sending reversed currents, but with only partial success.

With parallel conductors and telephone working the conditions are very different. The total energy expended in any circuit in a given time may be considered under

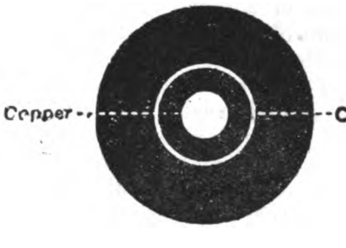

Fig. 4.

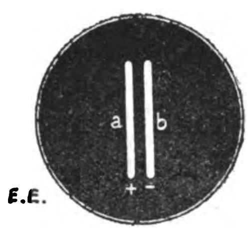

Fig. 5.

three heads: (1) that expended in overcoming resistance; (2) that expended in producing the electric field; (3) that expended in producing the magnetic field.

In each case we must consider the energy stored up and that dissipated. The former tends to retardation, the latter to work done, and therefore to reduction of efficiency. Careful regard must be paid to the directions in which the different disturbing forces act, for it may be that they oppose each other, and direct the energy into the original channel under modified and more favourable conditions. Thus, if the whole effect of the electrostatic field is neutralised by that of the electromagnetic one, the total energy developed is expended on the circuit itself, disturbances are eliminated and the service improved. This is the case of a metallic circuit having a microphone transmitter at one end and a telephone receiver at the other. The capacity of such a system will tend to store up a portion of the energy of each current, but the electromagnetic induction between them will tend to supply the deficiency. If the two wires of the loop be far apart, the influence of mutual induction will be much less than that of capacity. As they approach, the electromagnetic induction must increase at a greater rate than that of the electrostatic induction, until, finally, at the limit when they coincide, the one must exactly neutralise the other. This, perhaps, is better seen if we consider the case of a concentric cable; for, in this case, the number of lines of electric force does not increase, while the number of lines of magnetic force cutting the other conductors does increase rapidly as the outer conductor approaches the inner. The maximum induction from each source must take place when the two conductors are infinitely near each other, and this maximum must equal the primary current, for it cannot exceed it unless there were fresh creation of energy. Thus, as the separating dielectric becomes smaller and smaller the two effects approach each other closer and closer, until at absolute contact they annul each other. The result must be that if these be the only conditions present the time constant must diminish as the two conductors approach each other, and in the limit it must disappear. Twenty miles of concentric cable (Fig. 4), insulated with paper, were made and laid in the streets of London to test this reasoning, and comparisons were made with ordinary parallel cylindrical conductors, insulated both with gutta-percha and with paper and air. The result was very encouraging, but an unsuspected difficulty arose from the want of symmetry of the capacity of each conductor and the earth. The insulation resistance of each conductor was also different, and the result was that when the concentric cable was joined to overground wires, serious disturbances were experienced in the working circuits, which, however, were remedied by crossing the conductors of the concentric cable at several points, so that each side of the circuit was sometimes the inner and sometimes the outer conductor. This, however, is a cure that could not easily be applied to a submarine cable. It is clear that in such a cable symmetry of capacity with earth and of insulation is essential.

The experiment with the concentric cable shows that we have to consider not only the capacity between the two conductors, but that between each conductor and earth. Symmetry can be produced if the conductors be shaped and arranged as in Fig. 5. Only a certain number of lines

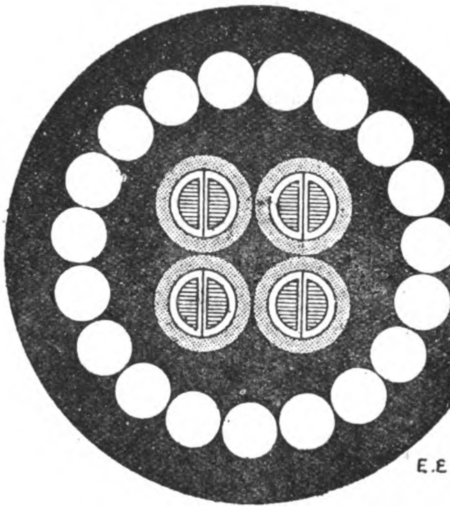

Fig. 6.

of electric force, dependent on the voltage present, can emanate from each conductor. The closer *a* and *b* (Fig. 5) are to each other, and the further they are from the earth, the greater the number of lines between the conductors and the fewer to the earth. The electric field is, in that case, confined almost entirely to the space between *a* and *b*. Taking the transverse action upon each element of such a core working telephones, each conductor is a source of periodic and opposite alternating electric force, and a displacement current passes through the dielectric that separates *a* and *b*, varying, not only with the electric forces and the specific inductive capacity, but with the frequency of the alternations. There is no storage of energy. It is dissipated as heat, but this heat, with the very small amount of energy expended in telephone working, cannot be sensible. Taking the longitudinal action per unit length of each conductor, since there is no storage but only a small expenditure of energy between the conductors, the rate of fall of voltage must be slightly greater than that required by Ohm's law. It does not, however, cause retardation, because that is the result of storage and release of energy. It is different, however, with the condenser action between each conductor and earth. Here there must be some storage of energy, but, for the reason given, this must be small; and in an insulated system like a telephone circuit, and with a thick dielectric sheath, the effect may possibly be neglected.

The problem resolves itself into a practical question: What is the best form to give the cable with our existing experience and our available materials? My present solution is given in Fig. 6. The conductors are insulated

Digitized by Google

first with paper and then with a thick coating of guttapercha. Paper only exists between the conductors. The cable is sheathed and compounded in the usual form. There are four circuits, instead of two, as at present in the London-Paris cable. With such a cable I have little fear of speaking between England and Germany, but to test the practical points that arise in the manufacture of such a cable it is proposed to make and lay a short one to the Isle of Wight. If my reasoning is correct, and so far experiment has confirmed it, then not only ought we to be able to speak to great distances, but the type of ocean cables must be revolutionised, for what is true for telephony would be equally true for telegraphy. Cables such as those across the Atlantic might, with the same weight of copper, be made to transmit a greater number of words per hour than they do now.

DISCUSSION.

Lord Kelvin had no doubt but that the construction shown in Fig. 6 would completely prevent the mutual disturbances in the cables, but he thought the capacity would be too much for practical purposes. In long cables the sluggishness would be greatly increased.

The **Author** said that if the frequency was not effected, good speaking might be obtained in spite of the retardation; but **Lord Kelvin** repeated that he thought the new form not so good as the concentric.

Prof. F. Bedell referred to the lack of symmetry in concentric cables, and to Mr. Preece's proposal to correct this by cross-connecting every few miles. He rather doubted the efficacy of this method and thought the effects might not be cumulative. It was rather like making lumps in one mile of road to correct holes in the previous mile.

Prof. Silvanus P. Thompson said that the advantages of the paper and air insulation did not consist merely in the difference of specific inductive capacity. The effects on the surface of the insulation when the cable was charged needed consideration, and this soaking in effect would be absent with air dielectric. He had some three years ago proposed to nullify the effect of capacity by artificial leaks distributed over the length of the cable. The method he proposed was to have two conductors, lead and return, in the cables, and to connect a third of high resistance between them at intervals.

Mr. Preece, in reply, agreed with Mr. Bedell that the crossing over of the conductors in concentric cable would not be possible with marine work. The air and paper insulation had great advantages over the guttapercha, both on account of the surface effect mentioned by Prof. Thompson and because the speed varied inversely as the specific inductive capacity. He would congratulate Lord Kelvin on the now universal acceptance of his law which first showed the truth of this. It was a fact that the heat used to heat up the dielectric relieved retardation, and he cited a case in which Prof. Vernon Boys had used strip conductors to increase the speed of signalling. He had often noticed that an increase in the possible speed of working had heralded a breakdown in the cables. The other points raised would be settled to some extent by the experimental cable now being constructed.

STREET-LIGHTING BY ELECTRIC INCANDESCENT LAMPS.*

BY WILLIAM GEORGE WALKER, M.I.M.E., A.M.I.C.E.

Having been consulted in reference to the installation of incandescent lamps in streets of several towns in this country and abroad, has led the author to communicate the following remarks. Street-lighting by the aid of incandescent lamps will probably receive serious consideration in the near future, principally in connection with the electric lighting of country towns and the by-streets of large cities. Great difference exists between the quality of the illumination required for the various streets of a large town. The payment of from £15 to £25 per annum for each arc lamp placed in the streets prohibits their use in the side streets, where the traffic is small. Arc lamps are undoubtedly the right thing for busy streets, but would prove an extravagant illumination for ordinary by-streets or roads of country towns. The difficulty has been only slightly met by placing the arc lamps at the corners of side streets running from the main ones. In side streets of large towns, and country towns where the population is scattered, the principal importance of the illumination is for the demarcation of the streets and roads. The light obtained from the ordinary gas-burner when placed at 50 yards apart is practically nil as an illuminant for the whole area of the street, yet its usefulness as a guide to traffic is obvious.

* Paper read before the British Association.

It may roughly be taken that the quality of the illumination necessary is of two kinds: firstly, where a flood of light is necessary on account of the nature of the traffic; secondly, where the light is necessary for the demarcation of the roads. The first quality has been met by the adoption of the arc lamp in series; it is the second which the author wishes to consider. At present very little street-lighting by incandescent lamps has been carried out in this country, and some of the few installations which have been put down have apparently only proved a partial success. It has, however, been tried with success on a fairly large scale in Brazil, North America, and on the Continent. It has been suggested that the current for the street lamps may be taken off the ordinary low-pressure mains that serve for house-lighting, etc. The current is not, however, laid in the majority of by-streets, and it will probably be many years before, if at all, it is adopted in all classes of houses; and even if a complete network of mains were laid for domestic and factory purposes there would be many objections to taking the supply from those mains, in addition to the inconvenience of switching each lamp in and out, as is the case with the ordinary gas lamp. Estimates show that the parallel system is generally impracticable on account of the comparatively great cost of the copper mains required to distribute small incandescent lamps in the streets. And, again, the overhead system would be debarred, on account of the weight of the cables. The parallel system becomes practical in congested districts and where natural water power can be obtained, as has been the case in several towns in Brazil, where there is abundance of natural water power, and also on the Continent.

It is due to the impracticability of adopting a "parallel system" of distribution on account of the cost and weight of the copper cables, that electric lighting has made so little progress in the lighting of side streets and country towns of this country. It has been felt that a way out of the difficulty was the adoption of the series system of distribution, whereby a small current may be employed running through all the lamps, allowing copper mains of small sectional area being used, thereby avoiding an expenditure on the mains. The number and candle-power of the lamps on the series circuits depending simply on the electrical pressure, the current being kept constant throughout the whole circuit (the voltage varying from a maximum at the positive terminal to a minimum at the negative one). The main difficulty against this system is that the failure of a lamp filament is liable to open the circuit and put out all the other lamps on the series, in spite of automatic switches.

The town of Temesvar, in Hungary, nearly 10 years ago adopted incandescent lamps for the lighting of streets with very satisfactory results; 750 16-c.p. lamps were originally put down on the multiple-series system—that is to say, in groups placed in series on the circuit, the lamps in each group being connected up in parallel. Each group consists of eight lamps in parallel, there being about 100 groups. In case of failure of a lamp, an automatic switch puts in circuit a resistance equivalent to the lamp. These appliances have been found to work well. The mains are overhead, fixed to telegraph posts, or to wooden arms let into the walls of the houses. The Municipality pay the company in whose hands the lighting is about £3. 10s. per annum for each lamp installed. During the first 1,200 hours of lighting only two out of 750 failed.

The series system of distribution with incandescent lamps has been installed in the parishes of Kingswood and Keynsham, near Bristol, and has shown considerable success during the 4½ years which it has been at work. As this is the only installation of its kind in Great Britain it may be interesting to give some details of the plant. The figures have been kindly supplied by Mr. Parfitt, the electrical engineer of the plant, and are up to the present date. At Kingswood about seven miles of roads and streets are lighted by circuits of two, two and a half, and three miles respectively from the central station. The lamps are spaced, roughly, at distances of about 60 yards, and are elevated at from 14ft. to 15ft. from the level of the road upon wood and iron posts, which also carry the

Digitized by Google

wires overhead. The sizes of the lamps vary from 100 c.p. in the main streets to 35 c.p. and 25 c.p. in the side roads. The 100-c.p. lamps are switched out at 11.30 p.m., and other lamps of 16 c.p. are put in circuit. The smaller lamps are switched in before the larger ones are cut out, so that the continuity of the lighting is maintained. There are 150 street lamps, of which 16 are 100 c.p., 52 lamps of 35 c.p., and 60 lamps of 25 c.p. The indicated horse-power of the engine at full load is 32. There is a penalty clause in the agreement of 10s. per lamp for all defective lamps per night; and it says something for the regularity of the supply, and also for the good working of the automatic switch devices, that the fines for the last year were nil. The station plant comprises a compound Davey-Paxman horizontal receiver type of engine, which drives by belting three dynamos—a dynamo and its exciter giving 800 volts and 12 amperes—for the public lamps; also a shunt-wound dynamo at 130 volts and 50 amperes used for private lighting, together with a battery of 394 E.K.-E.P.S. cells, which forms a reserve against breakdowns. The boiler is of 16 nominal horse-power, Davey-Paxman type, working at 140lb. pressure. The mains which supply the high-pressure current (800 volts) are 10 and 14 S.W.G., and are insulated. They are carried by slings from steel bearer wires, strung from oil insulators in the usual way. The low-pressure circuits are of bare copper, Nos. 8 and 12 S.W.G., also strung from oil insulators. A device in connection with the magnetic cut-out and automatic switch has been contrived by which a local circuit is called into action, and a current is made to pass to the station from any defective lamps through the steel bearer wire, and so this is a constant resistance per mile run. The current passing through a suitably calibrated ammeter is an approximate indication of the position of the defective lamp. This current also rings a bell and calls the attention of the attendant. The revenue from the street-lighting is £650 per annum, supplied at an approximate price of 2½d. per unit. The cost of production is about £550 per annum, which includes a sum of 5 per cent. on the capital for depreciation, leaving a profit of £100. Coal, at 8s. 6d. per ton, costs per unit output 0·387d.—total cost per unit output, 2·1d. Lighting hours are 4,250 per annum, or from sunset to sunrise. The total cost of the Kingswood station and plant was about £3,500. The author understands that negotiations are now going on for extensions of the system.

The chief characteristic of this installation is the automatic cut-out devised by Mr. Parfitt, so that the failure of one lamp does not affect the lamps in series with it, but only that lamp, and that only temporary. The circuit is divided into two branches taking equal amounts of current. Each lamp has in series with it an electromagnet. A resistance is placed as a shunt to the lamp; so long as the armature of the electromagnet remains away from the magnet poles no current will pass through the shunt. The normal current of the lamps will not lift the armature, but when a lamp breaks the double current will pass through this allied lamp and through the electromagnet, which will lift the armature and complete the circuit through the shunt resistance, which is equivalent to the broken lamp. Should the second lamp break, the whole passes through the resistance.

Other devices might be used for carrying out a series system. The author's reason for calling attention to the one used at Kingswood is that it has worked satisfactorily during the past 4½ years, and that he himself has tested it under several conditions and found it act efficiently. On the breaking of a lamp the allied electromagnet appears to act simultaneously, and no apparent flicker was noticed in the corresponding lamp. The installation certainly goes to prove that the series system can be made a practical success, and that automatic devices may be constructed that can be relied on.

The Urban Board of Eston have recently received estimates and tenders for lighting the scattered district of Eston, Grangetown, and South Bank with 32-c.p. lamps. The estimates were for replacing each gas lamp with a 32-c.p. incandescent lamp; the estimates were very low, and the borough surveyor, Mr. Stanthorpe, informs the author that had not the private gas company granted them large concessions from their last year's contract they would have at once adopted the incandescent system for the lighting of the streets. As it is, he thinks it only a matter of time when his Council will do so. These estimates were for an overhead series system. It appears perfectly clear that a series system with overhead wires is suitable for scattered districts, and that it is as cheap as gas.

There appears to be considerable superstition among electrical engineers that a series system for incandescent lamps is difficult to manage. This opinion has been fostered by the apparent failure of one or two installations in this country, but it was not far to look for the cause of these failures, and which should not completely condemn the system. The Board of Trade may eventually require all high-pressure mains to be placed underground, in which case many of the advantages of the series system would disappear, as it would not perhaps be worth while to go to the expense of trenching for such light wires. Now that it is possible to obtain lamps suitable for a voltage as high as 250, and when used in conjunction with a three-wire parallel system, it may of course be worth while to pay for the extra cost of copper, as the system would undoubtedly be more convenient. Any increase in the voltage of incandescent lamps renders the parallel system more practicable, but even if it were possible to employ a 400-volt incandescent lamp arranged on the three-wire system, the dynamos working at 800 volts, the cost of copper mains would be about double of that if a series system were employed. A high-tension alternating two-wire system has been considered working at 2,000 volts, with a small transformer for each lamp, reducing the voltage in the secondary to, say, 200 or 250 volts; the efficiency of the small transformers would be of secondary consideration compared with any saving in the costs of the mains, and there would be no trouble with automatic switches.

APPLIED ELECTRO-CHEMISTRY.*

BY JAMES SWINBURNE.

LECTURE II.

The pressure needed to cause a given decomposition is frequently calculated from the thermo-chemical data given in pocket-books. As a coulomb decomposes a given weight of, say, salt, and as the combination of the sodium and chlorine which produce that amount of salt give out a definite quantity of energy as heat of combination when they form salt, it seems at first sight that by dividing the quantity of energy by the quantity of electricity we should get the pressure corresponding to the reaction. Broadly speaking, the pressure needed to electrolyse follows the heat of combination, but care must be taken not to take wrong data. The thermo-chemical data quoted in books on general chemistry are mostly taken from a four-volume book of researches by Thomsen, and are not always quoted intelligently. It is generally necessary to look up the context to see exactly what the author means. The heat of combination of, say, zinc and oxygen may be found on examination to be the heat of metallic zinc burning in gaseous oxygen. Allowance must in many calculations be made for the elements in compounds changing their physical state. Other reactions have taken place in a solution, a precipitate being formed, in which case heats of solution are involved. In working with data from Berthelot's book allowance must be made for the old notation. In many cases people totally misapply these data. For instance, in calculating the E.M.F. of a Daniell cell we are not really concerned with the heat of combustion of metallic zinc in gaseous oxygen, though it frequently figures in such calculations in spite of the fact that oxide of zinc is not formed. These thermo-chemical data should therefore not be used blindly, and should only be employed by those who really understand what they are doing. Chemical reactions do not necessarily take place so as to give out the maximum energy, however, so these thermo-chemical data cannot fit.

Suppose we have two primary cells; suppose at the temperature of the air they give one volt; imagine them coupled together, back to back, so that there is no current; suppose those cells, like most primary cells, have a temperature coefficient so that the electrical pressure given depends on the temperature; suppose that at a certain higher temperature the cells give 1·1 volts; let one be kept at this temperature, and the other at the temperature of the air: we then have 0·1 volt available, and there will be a current backwards through the cold cell. The chemical work is just the same in the cells,

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

except that all that is done in one cell is undone in the other. The capacity for heat of the whole cell is not altered by any changes in the compounds contained in it, as the specific heat of a compound depends only on the elements that compose it. We thus have a simple example of the pressure not being in accordance with the heats of combination, as the heats of combination would give the same pressure for the two cells. We can put a small motor in the circuit of the two cells, and get work done without any chemical energy being used up, as the chemical action is the same in the two cells. As this would otherwise mean perpetual motion, it is clear that the work done by the motor must be accounted for by heat disappearing somewhere in the circuit. The only place this can happen is in the cells. One or both of the cells must therefore be taking a continuous supply of heat from its surroundings and giving it out as electrical power. The cold cell cannot be taking heat from its surroundings, for if it were, and if the heat were converted into power, we need only wrap the hot cell in a non-conducting jacket, and the system would give perpetual motion. The hot cell must, therefore, be abstracting heat from its surroundings, and giving more pressure than its chemical reactions account for. Let us, therefore, divide its pressure in two parts—the chemical E.M.F., E_c, and the heat E.M.F., E_h. We can call the chemical and heat E.M.F. of the cold cell E'_c and E'_h, and the temperatures of the cells T and T', T being the higher temperature. Now the pressure of the hot cell is $E_c + E_h$, and that of the cold cell $E'_c + E'_h$, of which E'_c and E_c are equal. So the difference of pressure is due to the difference of E_h and E'_h. The difference in this case is taken as 0·1 volt, but that is merely an example. This difference, $E_h - E'_h$, is the available part of the pressure for motor or other purposes, and it is due to heat taken in at the temperature, T. As in such cases only a portion of the heat is converted into work—namely, T − T'/T, the available pressure, which is entirely due to the difference in heat E.M.F., as the chemical E.M.F.'s cancel out, can be given thus:

$$E_h - E'_h = \frac{T - T'}{T} E_h$$

Transposing, we get

$$E_h = T \frac{E_h - E'_h}{T - T'}.$$

If we imagine T to be infinitesimally above T', T − T' is dT and $E_h - E'_h$ is dE_h, or dE, as the increase is the same for the whole pressure the cell. We thus find that

$$E_c + E_h = E = E_c + T\frac{dE}{dT}.$$

This is Helmholtz's equation, put in a way that may be easy to follow. It shows that where a cell or a vat has a temperature coefficient the pressure does not follow the heats of combination, but depends on the temperature coefficient in a definite way.

If the hot cell had given less pressure than the cold one, the current would have been in the other direction; but heat must still be taken in at the hot cell and a portion of it given out at the cold one. If a cell has its pressure higher than the chemical actions account for, it must absorb heat on discharging and give it out on being run backwards, and *vice versâ*. If a cell has a negative coefficient its pressure must be lower than the chemical action accounts for; so, if the hot cell has the low pressure, it will be run backwards; but the work done by the current against the back pressure is too small to perform the chemical work, and the extra heat to be taken from the surrounding matter. It may be asked where the heat is taken up; whether at the anode or the cathode? Though the *locus* of the disappearance of heat is not necessarily the seat of the E.M.F. of a cell, this brings us to another question, which though of purely theoretical interest, as far as applied electro-chemistry goes, may be discussed, the novelty of the view taken being my justification.

Seat of the E.M.F. in a Cell.

There is not any. After so many able chemists and physicists have been discussing this question for so long it may seem rather bold to make such a statement as this; but to a great extent the question is rather one of definition. It is commonly taken for granted that, say, a point on a wire must be at the same potential as itself, but this is not necessarily so. Instead of thinking of an electric circuit, with which we are a little too familiar to be able to see clearly what I mean, let us take a magnetic circuit, that of the magnets of a dynamo for example. Imagine a "unit pole" at one pole-piece. Let it move over to the other; the work it does will be the measure of the difference of the magnetic potential of the pole-pieces. If the pole is still allowed to move, say, along a small hole in the iron, it will go round the field magnets to the point from which it started, and will then make another tour round the magnetic circuit, and so on. Each time its path is a complete circuit, which is interlinked with the electric circuit—that is to say, with the field-magnet windings. The work done on the pole in each cycle is 4 π times the current-turns in electromagnetic C.G.S. measure, or 0·4 π times the ampere-turns in the practical system. Imagine that the iron is perfectly permeable; then all the work will be done on the unit pole in crossing the air-gaps, and the fall of the potential across them will be 0·4 π times the ampere-turns. There will be no force acting on the unit pole on its way through the small hole round the iron of the field-magnet circuit. It will be seen that every time the unit pole goes round it falls 0·4 π n c units of potential, so that every time it passes a given place it has fallen that amount. In other words, any part of the magnetic circuit differs from itself in magnetic potential by 0·4 π n c. At any point the magnetic potential has an infinite number of values, differing by 0·4 π n c. If we consider that the unit pole falls a height of 0·4 π n c in going across the air-gaps, in order to make up for this fall it would have to be raised the same amount on its way through the iron; but we have specially assumed the iron to be perfectly permeable, and there is no force at all on the way through the magnets. The force there really is due to the iron not being perfectly permeable, is in the same direction as that in the air-gap. A unit pole describing a circuit interlinked with an electric circuit thus falls in potential. Its potential is not raised the same amount at some part of the circuit. If it were, there would be no difference of potential between the poles. There is thus no seat of the "magnetomotive force," to use a loose term that is fashionable; in other words, there is no sudden rise of magnetic potential in the magnetic circuit.

Now take an electrical conductor, say, in the form of an incomplete ring, and imagine the end of a magnet to be moving slowly through the ring, so as to generate E.M.F. Suppose the wire has no resistance, merely for the sake of simplicity, and suppose the magnet pole is large enough to produce a volt at the rate it is going. If the coulomb is allowed to go from one side of the air-gap in the copper circuit to the other, it will fall one volt in potential, the fall of potential being measured by the work done—namely, one joule. Ear mark the coulomb and let it go round the copper to the place from which it started. As we have assumed the copper to have no resistance no work is done in this part of the circuit, and if there were any work owing to the resistance of the copper it would be in the same direction as when the coulomb crossed the air-gap. If allowed to go in the direction of the E.M.F. the coulomb is always falling in potential. Every time that coulomb passes a certain point in the circuit it falls one volt. Each point of the electric circuit has, therefore, an infinite series of potentials differing by one volt. It might be said that this cannot be the case, because the potential of a point on the conductor is defined as proportional to the work done by a unit quantity of electricity moving from there to the earth, or to an infinite distance. But it can choose various paths, and if it goes round the magnet pole several times it will add or subtract a volt for each time it goes round. At first sight the analogy between the electric and magnetic circuits does not seem very clear. The moving magnetic pole, however, corresponds with a magnetic current. A magnetic conductor is unknown, but just as there can be a displacement current of short duration, or a convenient current in an electric circuit, so there can be a displacement or convection magnetic current. The moving magnetic pole in this case corresponds to a convection current; if it had been stationary, but had been an electromagnet with increasing excitation, we would have had a magnetic displacement current. If a magnetic circuit with a magnetic current is interlinked with an electric circuit, there is cyclic difference of electric potential round the electric circuit. If an electric circuit with an electric current is interlinked with a magnetic circuit, there is cyclic difference of magnetic potential round the magnetic circuit.

The analogy between the electric and magnetic circuits is not popularly understood as well as it ought to be, and its clearness has been very much obscured by the unfortunate use of the term "electromotive force" for difference of potential or potential instead of for the rate of decrease of potential. We have thus "electromotive force" as the line integral of "electric force"—a term not much used—and magnetic force remains as the rate of decrease of magnetic potential. Still further confusion has been produced by treating permanent magnetic displacement as analogous to an electric current, and permeability, which is really the analogue of specific inductive capacity, as magnetic conductivity. To make matters still worse, the term "magnetomotive force" has come in to denote magnetic potential, while magnetic force remains in the legitimate sense of rate of fall of magnetic potential. These absurdities have been approved by international and other congresses and committees, but the so-called work of holiday meetings of people with idle summers should not be taken too seriously. The idea of the interlinked electric and magnetic circuits and their analogy and of cyclic potential is fully worked out by Maxwell. Heaviside, however, has developed the subject very fully, making it the basis of his treatment of electromagnetic theory. I do not know if there are any Germans who do not read English as well as an Englishman reads German badly, but if so, they will, if I remember right, find the ideas of Maxwell and Heaviside developed by Föppl without Heaviside's special kind of algebra. The idea of a magnetic current is, I think, due to Heaviside.

(To be continued.)

NOTES ON ELECTRIC CRANES.*

BY E. W. ANDERSON, A.M.I.C.E., M.I.MECH.E.

One of the earliest applications of electricity as a convenient medium for the transmission of motive power was to the driving of travelling cranes, and the fact that this, at that time, newly developed method of transforming heat energy into a subtle vibration and reconverting into work was so soon applied to this purpose shows that there certainly was a need for it. Now, after some 10 or 12 years' experience, it may be fairly stated that the system is not only a success, but is the very best method that has yet been devised.

The object of this paper is to give some of the experience the writer has had with electric cranes in practical use in the Erith Ironworks, trusting that it may be of general interest, while at the same time it is hoped that the discussion may elicit that of other users. A paper is to be read at the coming session of the Institution of Civil Engineers by Mr. H. W. Ravenshaw, on the application of electricity to cranes and lifts, in which it is understood a large number of figures will be given dealing with questions of efficiency, current consumption, etc., and for which the writer has supplied a certain amount of information. It would not therefore be quite fair to forestall this paper by giving any of this information now, and it is proposed to deal solely with practical points.

In May, 1888, Dr. W. Anderson, C.B., etc., then a member of the firm of Easton and Anderson, of Erith, conceived the idea of applying electricity to a 20-ton travelling crane in the foundry, and in due course this was carried out successfully. At the next meeting of the British Association he read a paper before Section G, in which this crane was described and illustrated, the results of some experiments with it being given as well. It is, therefore, not necessary to describe in detail the arrangements of this crane, as they may be found in that paper; but it will be sufficient to say that the several motions are controlled by gearing driven by three transverse shafts on the top of the girders, and which are themselves rotated in either direction at will from a longitudinal shaft through the medium of three nests of bevel wheels and friction clutches. The longitudinal shaft is driven by means of a double helical spur wheel and pinion from a five-unit shunt-wound motor made by the then existing firm of Elwell-Parker. Each motion has two gears by which fast and slow purchase may be given as desired. The shunt coils of the motor are always in circuit with the conductors, and the starting switch simply turns on the current through the armature and through the usual resistance coils, which are so arranged that they can be used to regulate the speed if necessary. The motor is started light—that is, moving only the longitudinal shaft—and when it has attained its proper speed the several movements can be independently worked in either direction as required. The conductor conveying the current consists of a piece of angle iron, having one face roughly ground up, fixed to the shop columns above the crane by means of wooden blocks, and upon which a brass contact-piece attached to the crane by a spring slides, while the return circuit is taken through the wheels on to the rails. The pressure used is 100 volts.

When first started there was, as might naturally be expected, some little difficulty and trouble. The friction clutches were not quite up to the mark, and had to be altered a little, and the fuses inserted in the dynamo circuit had an uncomfortable habit of melting at the most critical times, generally when a ladle full of melted iron was being manipulated. These mishaps at first raised some prejudice against the crane, but when they were got over by improving the clutches and by the simple expedient of putting in larger fuse wires and chancing a burn out, such prejudice gradually disappeared. The writer is aware that the remedy to the fuse difficulty is hardly one to be justified on scientific grounds, but practically it has proved quite successful, owing no doubt to the fact that the heavy currents are only on the armature for such a short time, that the heating from them cannot become destructive. The motor is frequently called upon to give 10 h.p. for a short time, and seems none the worse for it, while on one memorable occasion, when an accident occurred and prompt measures had to be taken, the crane is known to have lifted at least 35 tons, and to have been none the worse for it.

Shortly after this crane was started, and before it was quite in a satisfactory condition, a steam crane was purchased and set to work in the foundry on the same gantry, so that the two cranes could be admirably compared in a practical manner. It was of an ordinary type, having its own boiler, engine, and gear on the travelling crab, so that it was entirely self-contained. At the present time these two cranes are practically doing the whole work of the main bay of the foundry, and have been steadily running—except, of course, occasionally when under repair—ever since they were started. The result is, that while the electric crane was looked upon by the foremen and workmen with some little distrust at first, now it is much preferred to the steam one, and has all the most important work given it to do by preference. The atmosphere of a foundry provides an excellent test for the durability of electric machinery under trying circumstances, and in this case not only is there the dust and dirt arising from the foundry itself, but there is the steam and smoke from the other crane, which does not by any means improve matters.

When first installed considerable doubts were entertained as to the ability of the motor to work well in so trying a situation, but the practical result has quite dispelled any fears on that score. It is not easy to get any exact statement of the repairs that have been required, as no record has been kept of them, and the care of it has been through several successive hands; but it is found that they have been very small indeed, and much less than have been found necessary in the case of the steam crane. The friction clutches require occasional adjustment, and from time to time some new parts, while two new commutators have been fitted to the motor, and it was considered desirable to rewind the armature once, otherwise an occasional turning-up of the commutator and adjustment of the brushes has sufficed. The starting switch requires a little trimming now and then, and one or two new contact-pieces have been fitted. Of course, the other parts of the gearing have required attention as in all other cranes.

A great advantage which this electric crane possesses over the steam one is that the attendant has nothing to think of except his work and can give his whole attention to it. In the other case there is the fire and the feed-water to look after and be borne continually in mind, distracting attention from the work that is being performed, and even constituting a source of danger in case of its being neglected. Moreover, it is necessary for the steam-crane attendant to come to his work an hour and a half before general work begins in order to get up steam, and on Mondays this is increased to two hours, whereas, with the electric crane it is not required, as the dynamo supplying the current is driven by the main turnery engine, for which, of course, steam has to be got up by starting-time in any case.

An important matter in foundry work is to have complete command of the crane at all speeds, to be able to lift and lower at exceedingly slow rates, and by the smallest possible amounts, so as to be able to draw large patterns and put moulds carefully together. It has been found that the electric crane answers admirably for such purposes, thanks, no doubt, partly to the sensitive friction clutches, and partly to the resistances provided for slowing down the motor, and is much superior to the steam crane.

Having said so much as to its good qualities, one objectionable feature must be pointed out, and that is, the noise made by the first-motion gearing. In the first instance, the motor running at 1,200 revolutions per minute drove the longitudinal shaft by means of an ordinary cast-iron spur wheel and pinion having a ratio of 8¼ to 1. The rattle made by this was terrific, and as it was found that, owing to the narrowness of the space available between the crane and the shop columns, mortice gearing, which would of necessity be broader, could not be got in, it was decided to substitute double helical-toothed wheels for the straight-toothed ones. The result was not so good as might have been expected, and at first the noise was nearly as great; but after having worked a little, so that the faces of the teeth had worn into better order, it improved a little, but still was very objectionable. It was then suggested to block up the triangular spaces between the arms of the wheel with wood, in order to deaden the vibration, and this did a great deal of good, as it converted the sharp, noisy rattle into a dull rumble, which was much less objectionable, and in this manner the crane has worked ever since.

The foundry crane promised to be so successful, that in May, 1889, it was determined to adapt electrical driving to a 15-ton crane in the main bay of the turnery. None of the cranes in this department had, however, been arranged with a view to the ultimate application of power driving like that in the foundry, but were simply fitted with ordinary hand-gear, so that a different system altogether had to be adopted. The crane had its gearing all fixed to bearings attached to the main girders, and the load was lifted by a falling block and four-part chain suspended from a small travelling carriage running on rails in the bottom flanges of the girders. The cross traversing was performed by a pair of pitch chains attached to this carriage and passing over sprocket wheels geared to the handles. The hoisting barrel was fixed at one end of the girders, and suitably geared to the handles, an automatic brake for lowering being also fitted. The chain after leaving the barrel was carried over guide rollers to a pulley at the other end of the girders, from whence it passed to the travelling carriage and falling block, and was finally anchored at the gearing end of the girders. The longitudinal traverse was worked in the usual manner by gearing connected with the running wheels of the end carriages, the opposite sides being connected together with a cross-shaft. On each side of the main girders there was a wooden platform for the men to stand when working the various handles. It was therefore evident that in this case the simplest thing to do was to remove the handle shafts, substitute belt pulleys for

* Paper read before the British Association at Liverpool.

Digitized by Google

them, and drive from three separate reversible electromotors placed on the wooden platforms.

The company had not at that time commenced the manufacture of electric machinery themselves, and therefore three "Manchester" motors of suitable sizes were obtained from Messrs. Mather and Platt, provided with jockey pulleys, so as to run with very short belts, and brushes arranged so that the armature might revolve in either direction, and were duly fixed, as described, on one of the platforms. On the other platform a framework was fixed carrying three reversing switches and resistances, each controlling one motor, and a foot lever connected with the automatic lowering brake was arranged conveniently for the attendant. The crane is worked simply by the manipulation of these three switches and the lowering lever, while from the position in which they are placed an excellent view of the work being done can be obtained. The crane is driven by the same dynamo that supplies that in the foundry, the voltage being therefore 100, and the hoisting, cross traversing, and longitudinal traversing motors are respectively 10-unit, 1½-unit, and 2½-unit machines, all being shunt wound, with a few series coils to assist them in starting under full load. The current is collected in a different way to that described for the foundry, the arrangement having been suggested and carried out by Messrs. Mather and Platt. Two bare copper wires about ¼in. diameter are suspended parallel to each other and about 8in. apart by means of earthenware insulators from every sixth roof principal, making thus a series of loops, each 60ft. long, extending all down the shop, a length of nearly 600ft., and with a moderate amount of sag given to them. A standard is fixed at the outside edge of each platform, and thus, as far apart as possible, directly under the two conductors, and each one carries two insulated brass plates, one under each conductor, and at such a height that except at the insulators and a few feet on either side of them the wires are able to rest upon them. The plates on the two standards, which are under the same conductor, are electrically connected together and to the switch frame.

It will now be understood that wherever the crane is, the conductors will be resting on one or other pair of the contact plates and sometimes on both; because, while at or near the insulators the conductors are held up clear of the plates, a few feet on either side they sag down so much that they come in contact with them, and the distance between the two sets of contacts is sufficient to prevent at any time both sets being in such a position as to be simultaneously clear of the conductors. By this means the supporting insulators are easily passed. The wires were not put up quite carefully enough in the first instance, and the crane used sometimes to stop from all the contacts getting clear at once, but a little readjustment soon put this right, and it has worked well ever since. This crane has worked very well always, and has given no trouble at all. Owing, however, to the motors being made to reverse, the brushes have to be placed on the horizontal axis of the commutator, and thus no lead is given them except that due to the small arc of contact, the result being that there is always some sparking, and the life of the commutators is less than in the foundry crane, where practically sparkless running is obtained. In the shorter time that this crane has been at work three new sets of commutators have been fitted. Likewise the switches, from being so much more used, require more repairs than that of the foundry crane, and recently it has been found necessary to put in a complete new set. With these exceptions, however, but little repairs are needed, as there are no friction clutches or anything liable to much wear. The conductor contact plates occasionally require renewal, but this is a very small matter, and the conductors themselves are in very good order. The system of driving the gearing from the motors by means of belts makes the working of this crane practically noiseless.

As already stated, experience has convinced the writer that, at any rate for travelling cranes, electricity is more satisfactory than anything else, and there can be but little doubt of its cheapness. It is not possible to make any actual experiments to determine the useful work done per hundredweight of coal or anything of that sort, to settle such a point as this absolutely; on account of the intermittent nature of the work and the variations of the power required, added to the fact that no measurement of the energy expended in traversing can be made at all, except at the motor itself, in which case the loss in the gearing must be assumed: and as the same applies to all similar cranes however driven; the comparative cost of different systems can only be arrived at by common-sense reasoning.

Electricity has the following economical advantages: the current may be generated by a highly economical engine, and, therefore, at the cheapest possible rate; the loss in transmission to the motors may be kept very small without serious initial outlay, as the distance of transmission is usually very small, and the motor will only use current in approximate proportion to the work it has to do. On the other hand, however, there is perhaps rather more loss in the gearing than in some of the other methods of driving, on account of the great reduction in speed that it has to effect. Compare now the self-contained steam crane, such as that in the foundry. Both boiler and engine are necessarily much less economical than need be used for electric crane driving, and it would probably be fair to say that a given power generated in this manner costs three to four times as much, though as a set-off against this the engine is close to its work, and the losses of conversion and transmission of the electric energy are avoided, as well as some of that in the gearing. The net result, however, must be considerably to the advantage of the electric system.

Attention has already been called to the necessity for the attendant to come an hour and a half before the crane is required in order to get up steam, and this, together with the expenditure of coal in getting up steam, makes a considerable extra expense, which is avoided where the cranes are driven from the main factory boilers. A small item of expense is also due to supplying the crane with the fuel and water, which, of course, have to be lifted up to it.

The comparison of electrically-driven cranes with those worked by other modes of transmission is more difficult, because all such methods may employ an economical engine as the generator of the power, and so far may place themselves on a par with electricity; but whether the transmission is effected by wire ropes, cotton ropes, or by a square shaft a large amount of gearing is involved which must always be running and absorbing power, no matter what kind of work the crane may be doing. The writer's opinion is that, while for short gantries such methods compare well with electricity from an economical point of view, for long ones, such as in the Erith works, they cannot approach it. Pictures to yourselves a shop 600ft. long having, on the one hand, either a square shaft continually running on one side of it with the numerous bearings requiring of course continual attention in keeping them properly oiled, or else a wire or cotton rope with the array of pulleys and their bearings required by it; and, on the other hand, two small copper wires suspended in the roof out of the way and requiring no attention whatever. In such a case there can be no question as to the best system.

As regards repairs, the writer is only able to give personal experience derived from a 20-ton crane driven by a wire rope in one bay of the high erecting shop at Erith. The longitudinal travel of this crane is only 120ft. It has been found that a new rope is required every year, and the cost of this, together with the splicing and putting up, comes to about £10, so that the expense on this score alone has probably exceeded considerably the electrical repairs on either of the electric cranes, taking an average over the eight years they have been at work. Obviously, if this rope-driven crane had the same travel as the others, the cost would be very much heavier.

It has been urged by some that a more skilful, and therefore better paid, attendant is required for an electric crane than for the ordinary types. The experience at Erith has shown that such is not the case, and any labourer of ordinary intelligence will very soon acquire what little special knowledge is needed to keep the electrical machinery in proper order.

In considering the general design of electrical travelling cranes, several points present themselves to which attention may be directed. Is it best to have one motor to work all the three motions, or a separate one for each? There is a great deal to be said on both sides of this question, and, taking it all round, the writer is disposed to think that there is not much to choose between them. The single motor is best from an electrical point of view, as it avoids the necessity of reversing, saves a good many connections, and gives only one high-speed machine to look after. On the other hand, it entails the use of friction clutches or their equivalent, and a good deal of gearing to properly control all the motions. The three-motor system is more economical in power, as the motors are never required to run light as the single motor has to, and therefore the small current taken under such circumstances is saved. The control may be effected entirely by switches, which are very easily worked, and may be even operated from below without anyone being on the crane at all. If two or three motions are being operated simultaneously, the speeds of them can be independently varied if desired, whereas in the single motor arrangement this cannot be done, as any variation of the motor of course affects all the motions equally. On the other hand, the motors require more frequent repairs, and there are three commutators and sets of brushes to wear out as against one in the other system—though, of course, each only does one-third of the work. The fact, however, remains that the reversing motor commutators wear out more quickly than the other even with the lesser work and with a much cleaner situation to work in.

A consideration that constantly arises in the application of electric motors is the best system to adopt for reducing their usual high speed to the slow one often required—as, for instance, in crane work. In the cranes that have been described, unquestionably the belt reduction is by far the best, not only for its noiselessness, but also on account of the absence of vibration, which is considerable in the case of the gear reduction. The motor of the foundry crane does not seem to have suffered much from this vibration, but cases have occurred where the jar of spur gearing has damaged armature windings, and it is therefore best not to run any risks, but use

Digitized by Google

some other form of reduction gear where practicable. Mortice wheels, with wood teeth, are of course better than either ordinary spur or double helical gear. Worm gearing is often a very convenient means of effecting the reduction, and is much more economical when properly made than is generally supposed. The writer's firm have used it very considerably in cases where other forms of gear were not suitable. It should be enclosed in an oil-tight casing, so that ample lubrication of all parts may be obtained, while dirt is excluded. The worm should be, by preference, on the top of the wheel, as it makes it more easily accessible, and the thrust should be taken upon properly constructed ball bearings. The angle of the thread is an important factor in the economy of the gear, and, in common with all the other details, requires careful consideration to get the best results. As a matter of fact, it is found that for economical results a treble-threaded worm is about the best to use, while double thread and single thread of ordinary proportions are less good.

From some experiments that have been made at Erith, it may be taken that the efficiency—that is, the ratio between the output and the input—of an ordinary single-thread gear, including the losses in the thrust and the wheel shaft bearings, should not be less than 52 per cent., a double-thread gear should be not less than 68 per cent., while a treble-thread gear should be not less that 75 per cent. A better result still may be obtained from quadruple-thread, but it is not so generally useful and is rather troublesome to make. Better results than these have been obtained, and in one carefully-conducted trial with a treble-thread gear that had been running for some time and had worked all the surfaces into the best possible condition, the combined efficiency of an electric motor giving out about 9 h.p. and the worm gear, including the thrust block and shaft upon which the Prony brake for testing was fixed, was as high as 85 per cent. This, however, cannot be relied upon in ordinary practice, especially when the gear is new, and therefore the figures given above are to be recommended for general use.

Friction gearing is occasionally employed, and if properly made and adjusted is good, at any rate, for small powers. The best form that the writer is acquainted with is Hollick's patent, which has been successfully used for crane work, giving good efficiency, and which may be thus described: The shaft to be driven has a large flat-faced pulley keyed to it, while another similar but smaller pulley is carried by bearings in a swinging frame in such a manner that the two pulleys are in the same plane, but separated from each other a short distance. Round them an endless belt is tightly stretched. The motor is supported on a flexible base, and has on its spindle a pulley made of compressed paper with a perfectly flat face, the size being rather larger than the space between the two iron pulleys. The ratio of reduction is given by the ratio of the diameters of the large iron pulley and the paper one. By exerting a slight pressure on the swinging frame, the paper pulley may be caused to wedge itself between the other two with considerable force, and if the motor is set in motion, the two iron wheels will both be driven by the paper one, the smaller transmitting its power to the larger by means of the belt, which also takes the thrust and prevents any stresses on the bearings. By making the motor base flexible, the paper pulley adjusts itself so as to bear equally against the two iron ones. Of course, to get the best results, this gear requires careful design and manufacture.

It will be interesting to make a comparison between hydraulic power transmission and electricity as applied to crane-driving. There can be no doubt that the hydraulic system is a very simple and convenient one in cases where the power has to be applied from a more or less fixed position, and is especially suitable where the work to be done is fairly constant, as, for example, a crane that always has to lift approximately its full load. In such a case the power may be used to its full advantage, which with variable work cannot be the case, except by the employment of double and treble powered machines, which to a certain extent adjust the water expended to the work it has to do. In this respect electricity has an advantage, as the motor has an inherent power of automatically adapting the amount of current it uses to the work that is demanded of it, though not quite in direct proportion. The motor, therefore, adjust itself to all loads, while the hydraulic machine can only do so in steps, so that the former must be more economical. Moreover, the motor does this without the aid of any external devices, whereas the hydraulic machine requires a complicated and expensive arrangement to effect the result. But hydraulic power can often be applied in a much more direct manner than electricity, as the latter almost always requires the high-speed rotation of the armature to be converted into a lineal movement in the hoisting arrangement of cranes or lifts involving a good deal of gear, which is, as a rule, not needed by the former. It is evident, therefore, that every case must be judged on its merits, and that sometimes one form of transmission will be more suitable, and sometimes another. But in the case of the particular kind of machinery with which the paper has been more especially dealing—namely, travelling cranes—there can be but little doubt that the electric system is much more advantageous, mainly on account of the great difficulty in satisfactorily taking the high-pressure water to the moving crane, especially with such a travel as the Erith cranes, say 600ft.

A hydraulic travelling crane was made at Erith a few years ago for the new ranges of the War Department at Shoeburyness to general designs furnished by the Royal Engineers, and this is the only instance the writer knows of where this method has been used for a true travelling crane. The lifting was performed by a direct-acting hydraulic cylinder, which would, of course, use as much water to lift one ton as 150 tons, the maximum for which the crane was made, and the two traversing movements were actuated by a rotary hydraulic engine driving a system of shafting and gearing. The principal feature of interest was, however, the method of transmitting the power to the crane, which travelled over a gantry 130ft. long. At the centre of the gantry on one side was a large hose keel containing a coil of Sphincter Grip armoured hose, one end of which was coupled to a hollow trunnion, through which the water was admitted to the coil, and the other to a swivel coupling on the crane. The hose was about half the length of the gantry, and thus, according to which side of the centre the crane was, and to the direction in which it was travelling, so the hose coiled or uncoiled from the drum, arrangements being made by means of weights and gearing for the drum to coil up the hose as the crane approached it. The exhaust ran into a continuous gutter laid down all along the gantry. This arrangement worked well, but is clumsy and expensive. The hose requires occasional renewal, and the system could only be applied satisfactorily to short gantries. Contrast this with the simplicity of electric transmission over any gantry, no matter how long it may be, and the advantage will at once become apparent. Besides, it would not be easy to work more than two cranes over the same piece of gantry, one having its coil on one side and one on the other; while with the electric system any number of cranes may work off the same conductors and over the same gantry, provided only the conductors are large enough to carry the required current.

In conclusion, the author would like to say that the paper does not pretend to be in any way an exhaustive treatise on the subject, but he thinks that the few notes he has put forward are sufficient to show that he had good grounds for making the statement at the commencement that electricity was the best method of applying power to the working of travelling cranes.

LEGAL INTELLIGENCE.

ELECTRIC LIGHTING PAYMENTS.

At Cardiff Police Court on September 22 (before Councillor E. Thomas and Mr. L. Samuel) a claim was made against William and Nesley Pedlar, umbrella manufacturers, 113, Queen-street, for electric energy supplied.

Mr. W. H. Andrews (deputy town clerk), in supporting the claim, stated that this was the first case of the kind under the Electric Light Act, and the summons was issued to show that the magistrates had jurisdiction over electric light rents. The summons was taken out under the Electric Light Act, 1882, which incorporated Section 40 of the Gasworks Clauses Act, 1871, and gave them power to recover as a civil debt.

It was stated in evidence that on July 29 the sum of £9. 18s. 6d. was demanded, and payment was promised, but nothing had been paid. There was another sum of £6 4s. 10d. due, but that, again, had not been paid.

The **Magistrates** made an order for payment accordingly, being satisfied that plaintiffs could recover in the police court.

COMPANIES' MEETINGS AND REPORTS.

ELECTRICAL COPPER COMPANY, LIMITED.

The statutory general meeting of this Company was held on Monday at the Company's offices, 14, Sherborne-lane, E.C., Mr. H. M. Matheson (the chairman) presiding.

The **Chairman** said the meeting was a purely formal one, but he might inform those shareholders present that the patents had all been transferred to the Company. There had been applications both from Germany and the United States with reference to the disposing of their patent rights, but the Board preferred to await the results of the works which they were about to erect at Widnes before parting with any of those rights on the Continent or in America. They had secured suitable land at Widnes for the erection of the works, on a lease of 999 years. The plans of the works were nearly completed, engines and dynamos had been ordered, and, according to the dates when all the machinery should be delivered, they would be in operation early next year. The experimental works at Paris had been taken over by the Company. These were sufficient for the manufacture of commercial samples, and numerous such samples had been made and reported upon by experts both in England and on the Continent. Numerous tests had been made by Messrs. Kirkcaldy and other experts, which had proved the superior strength and quality of the copper made,

Digitized by Google

A complete series of these tests was now being carried on, and certificates would be issued to enable engineers to judge of the suitability of the Company's copper for the purposes of their work. In reference to the preference shares, they had issued 100,000, and these had been allotted; but there were still 50,000 left, which might be issued by-and-by.

There was no resolution for the meeting, and the proceedings ended with a vote of thanks to the chairman, proposed by **Mr. C. Meyer** and seconded by **Mr. C. H. Hills.**

RAND CENTRAL ELECTRIC WORKS, LIMITED.

The report of the directors for the 15 months ended June 30 last states that the statutory meeting was held on July 30, 1895, since when three calls of 5s. each have been made in order to meet the payments becoming due to the contractors, Messrs. Siemens and Halske, for the erection of the works at Brakpan and the shipment of plant and materials for the main line and mine installations. During the period under review £116,306 has been expended in compliance with the obligations under the equipment contract. The directors have been able to place the sums not immediately required on deposit at satisfactory rates. The interest thus earned up to June 30 last amounts to £2,999 as it appears in the balance-sheet. The cession of all contracts entered into by Messrs. Siemens and Halske prior to the formation of the company having been duly completed and registered at Pretoria, the fully-paid 25,000 vendors' shares in respect of and in payment for such contracts were issued in April last. The political troubles in the South African Republic during the early part of this year have somewhat hampered negotiations for the supply of electric power. Contracts, however, for amounts aggregating about 1,200 b.h.p have been practically completed. Other negotiations are in progress, as a result of which the directors anticipate that the remaining available capacity will be placed. The total capacity provided for in the equipment contract is 2,100 b.h.p. The building operations at Brakpan (central station) were commenced about September 1, 1895, and up to the middle of August, the date of the last report to hand from Mr. N. J. Singels, the general manager, the iron structure for the engine-house as well as buildings and several houses for the staff, were completed. The engine-house has already been roofed for the greater part, and about half the walls have been covered with corrugated iron. The foundations for the boiler-house and the two first engines were also ready. The branch railway line from the Netherlands Railway to the central station is completed, and has already proved to be of good service, especially for the transit of the plant and heavy machinery. About 900 iron poles have been erected for carrying the main wire, which is to run from the Brakpan works to the Paardekraal Farm, and the laying of the wires has been commenced at the Brakpan end. The unfortunate labour conditions in the Transvaal during the first few months of this year have necessarily caused some unforeseen delay in the erection of the works. Some further delay has arisen owing to a recent railway accident at Boksburg, by which several parts of the machinery in course of transit were damaged, necessitating their replacement from Europe. No efforts however, are being spared towards completion of the works, and, considering the frequent troubles which mining companies at the Witwatersrand experience in connection with the transport of materials, the probable delay in the supply of power by the electric works may be considered as insignificant.

The annual meeting of the Company was held at Winchester House yesterday (Thursday), Sir C Rivers Wilson, G.C.M.G, C.B., in the chair. The report and balance-sheet were taken as read.

The **Chairman**, in moving the adoption of the report, said although the works were still in course of construction, it was anticipated that they would be completed and in operation very shortly after the date limited by the contract—viz., November 3 When at work their machinery would be capable of an output of 2,100 b h.p., and they had already concluded absolute agreements with 10 firms in the neighbourhood, who would require about 1,200 h.p., and operations were very far advanced with five other companies who would take about 600 h.p. The price agreed to be paid was £45 per horse-power, as estimated when the company was started, so he thought they would soon be securing good profits on their undertaking.

Mr. A. Brakhan, a member of the local board of directors at Johannesburg, gave a satisfactory description of the works, and spoke very highly of the Company's prospects and relations with the surrounding mines and other undertakings.

Mr. August Barsdorf seconded the adoption of the report, and it was carried unanimously.

Messrs. Alfred H. Märker and G. Zwilgmeyer were re-elected as directors; and the auditors, Messrs. Price, Waterhouse, and Co., were also re-elected.

A vote of thanks was passed to the chairman for presiding.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Paris.—For the electric lighting installation of the Collège Chaptal on August 29, the lowest tender is stated to have been that of Lacarrière et Cie.

Bucharest.—Tenders will be received at the Mairie, Bucharest, on November 16 for a water-power electric generating station at Grozavesti. There will be two stand-by steam-engines.

Leyton.—Tenders will be received by the Urban District Council on October 6th for installing the electric light in the public library. Particulars are obtainable at the surveyor's office, Town Hall, Leyton.

Madrid.—Tenders will be received on October 12 by the Direccion General de Correos y Telegrafos at Madrid for the supply to the Spanish Government of 60,000 telegraph insulators. The upset price is 1 peseta (9½d.), and a 10 per cent. security will be required.

Berlin.—The construction of an iron bridge at Gitschiner-und-Skalitzer street in connection with the electric tramway is open for tender. Application is to the Königl. Regierungs und Baurathes Bureau, Markgrafenstrasse 94, Berlin, and the date is September 28.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Brussels.—Tenders will be received on October 21, at the Bourse Brussels, for installing the electric light at the Arlon Railway Station, including the offices and works. Particulars are obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Leeds.—The Council require tenders for the supply and erection of No. 2 overhead travelling cranes for the engine-house of the tramways electricity generating station, The Calls, Leeds. Tenders, endorsed "Tender No. 8 for Cranes," must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than 12 noon on October 13. Particulars, plans, and forms of tender may be had from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

Blackpool.—The Tramways Committee of the Corporation require tenders for the construction of the Station-road, Dickson-road, and Warbrick-road tramways. The contract will include the laying of rails, points, etc., excavating, concreting, paving, and making good the roadway. The Corporation will provide all ironwork and setts. Drawings may be seen and specification and bills of quantities obtained on application to Mr. J. Wolstenholme, borough engineer, St. John's Market-buildings, Market-street, Blackpool, on deposit of £2, which will be returned on receipt of a bona fide tender. Sealed tenders to be delivered at the office of Mr. J. Wolstenholme, C.E., borough engineer, by 12 noon on 26th inst., addressed to the Chairman of Tramways Committee, and endorsed "Tender for Tramways." The person whose tender is accepted will be required to undertake to observe the standard rate of wages and working hours applicable to the particular trade.

Morley.—The Electric Lighting Committee of the borough of Morley are prepared to receive tenders for the supply and erection of the following plant. (The whole bound up in one specification; price £2. 2s., returnable on receipt of a bona fide tender): Section A—Boiler-house plant: Lancashire boilers and fittings, feed pump, etc. Section B—Engine-house plant: steam alternators and exciters, motor alternator, accumulators, steam and exhaust pipes, valves, etc. Section C—switchboard and instruments. Section D—overhead crane. Section E—underground work: cables and stoneware culverts. Section F—transformers and switchboards. Section G—arc lamps, posts, and accessories. Section H—meters. Tenderers are at liberty to tender for any section, but not for part of a section. The ground plans of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer to the Corporation, Ormond House, Great Trinity-lane, London, E.C., on and after Wednesday, September 16, on payment of £2. 2s. for each copy, which sum will be refunded on the return of the specification, filled up with a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to the town clerk, Mr. R. Borrough Hopkins, at the Town Hall, Morley (Yorks), and be delivered on or before Wednesday, October 14.

Digitized by Google

RESULTS OF TENDERS.

Dewsbury.—The Governors of the technical school have accepted the tender of Mr. Richmond Turner for an installation of electric light in the school.

Dantzig.—For the supply of incandescent lamps for the Royal Factory at Dantzig, R. Behrendt, Berlin, tendered at 49pfg. and 54pfg. for 16 c.p. and 35-c.p. lamps, and Pintsch Bros., Berlin, at 62pfg. For carbons, the Actien Gesellschaft vorm. Ch. Schmelzer, Nuremberg, tendered at 13pfg. and 10pfg. the pair, according to size. There were other tenders, which were not considered as the samples did not fulfil requirements.

BUSINESS NOTES.

Theatre-Lighting. — The Comedy Theatre is being fitted throughout with an installation of electric light.

Hoylake.—The District Council have resolved to make application for power to light the district by electricity.

Wimbledon.—The District Council have decided to apply for a provisional order for lighting the parish by electricity.

Stalybridge.—The Town Council have made application to the Postmaster-General to establish a general telephone call office in the borough, and to extend the telephone.

Cape Town.—The trial trips of the electric tramways have proved quite successful, and it is stated that a complete system for the town and suburbs will be laid down.

Cherbourg.—It is stated that the French Government have decided to put down plant for the annealing of armour plates by electricity on the Thomson-Houston system.

Bangor.—At the meeting of the Council a formal resolution was passed instructing the clerk to apply for an electric lighting provisional order in the next session of Parliament.

Perth.—The directors of the Highland Railway Company have, it is stated, sanctioned the proposed introduction of the electric light into the carriages running on the through trains between Perth and the North.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending September 20 amounted to £1,214, as compared with £1,239 in the corresponding week of the previous year, being a decrease of £25.

Southampton.—The negotiations by the Corporation for the acquirement of the electric lighting undertaking are now being carried on. The Local Government Board recently sanctioned the borrowing of £54,000 for the purchase.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending September 18 were £2 317. 4s. 10d., compared with £2 045 4s. 8d. for the corresponding period of last year, being an increase of £272. 0s. 2d.

Brighouse.—At the meeting of the Town Council it was decided to affix the corporate common seal to an agreement between the Corporation and Mr. A. B. Brook electrician, Brighouse, for the sale and purchase of his electric lighting plant within the borough.

Simla.—According to information dated from Simla, August 29 last, out of 11 firms who applied to the municipality for full particulars relating to the electric lighting scheme, only two submitted tenders. Neither tender had at that date been accepted.

London.—Messrs. J. Mowlem and Co, the contractors for the Waterloo and City Railway, have undertaken the contract for the construction of the new line from the Monument to Islington for the City and South London Railway, and the work will be proceeded with forthwith.

Motorcars.—At the annual meeting of Palmer's Shipping and Iron Company, the Chairman stated that they had arranged to utilise a portion of the plant in the manufacture of cycles, and when the time was ripe for them they proposed extending the manufacture to motorcars.

City and South London Railway.—The returns for the week ended September 20 were £871, compared with £831 for the corresponding period of last year, being an increase of £40. The total receipts for the half-year 1896 were £10,887, compared with £10,147 last year, being an increase of £740.

Bexhill.—A letter from the parliamentary agents in reference to the steps to be taken with regard to the proposed insertion of a purchase clause in the Bill about to be promoted by the electric lighting company was read at the Urban District Council meeting and referred to the Highways Committee.

Armagh.—In the report of the meeting of the County Asylum Board which appeared in our last week's issue the tender of Messrs. Inrig and Chester, London, was wrongly stated as being that of Messrs. Twigg and Chester. The price quoted by this firm should also have been given as £1,891, and not £1,961.

Fort William.—A new feature of the agricultural show this year was an exhibition of electric motor power as applied to farm implements and for cooking purposes, given by the electric lighting company. The experiments proved quite satisfactory. A butter-making demonstration was also given, the separator and churn being worked by electricity.

Walsall.—The Electric Lighting Committee reported at the Town Council meeting that they had given instructions for the cable to be laid in Freer-street for a distance of 75 yards from Bridge-street, at an estimated cost of £45, and they recommended that an additional transformer, at a total estimated cost of £1,000, be fixed in the transformer station at St. George's Hall. This was agreed to.

Eastern Telegraph Company.—The directors announce the payment on October 15 of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares for the quarter ending 30th inst., and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ending June 30.

Tunbridge Wells.—The Mayor, in commemoration of his year of office, has offered to completely instal the General Hospital with the electric light, and the governors have accepted the kind offer. The whole of the interior of the building is to be lighted, including the seven principal wards, the operating theatre, dispensary, and offices, while in the operating theatre the installation is to be of a very complete character.

Budapest.—The Hungarian Government has authorised the making of an electric railway between Budapest and Trieste by the Société de l'Industrie Electrique de Genève, which has deposited caution money to the amount of 3,000 000fl. in the Hungarian treasury. Starting from Budapest, the line is to follow the shore of Lake Balaton and then pass by Balaton, Fured, and Csakathurn, to terminate at Trieste. There are no considerable engineering difficulties to be overcome in this long line.

Eastern Telegraph Company.—The directors announce the payment on October 15 next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum, on the preference shares of the Company for the quarter ending September 30, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended June 30. The register of transfers will be closed from October 8 to October 15, both days inclusive.

Kidderminster.—On the recommendation of the General Purposes Committee, Messrs. Dyson and Co.'s bill of costs for business connected with the Council's opposition to the Kidderminster and Stourport Electric Tramway Bill, amounting to £34. 12s. 1d., was ordered to be paid at the last meeting of the Town Council. The Town Clerk, replying to a question, said he did not think the tramway would be commenced yet, as land had to be purchased and other preliminary arrangements made.

Appointments Vacant.—The Corporation require a thoroughly competent man as clerk of works for the foundation work in connection with the extension of the central electric light station, Bristol. Applications, stating age, salary required, and accompanied by copies of recent testimonials, to be sent to Mr. Frank Wm Prosser, secretary, Electricity Department, Temple-back, Bristol, by October 3.—The borough of Salford advertise in this week's issue for a good cable-jointer at £2 per week. Applications to be in by 30th inst.

Leicester.—At the meeting of the Board of Guardians the Lighting and Ventilating Committee reported that Mr. Hind had prepared an approximate estimate for lighting the Board room, committee-rooms, registrars' and clerks' departments with electric light, for the sum of about £60, which was recommended for adoption. The question was raised by Mr. Goddard as to the increased cost of the electric light as compared with the present mode of lighting, but there was no serious opposition to the proposal, which was eventually carried.

Dover.—At the meeting of the Town Council, Councillor G Fry asked when they were going to have a report from the Town Ward Committee in regard to the lighting of Biggin-street. Councillor Barnes said it would be ready next week. Councillor Fry said he was told that there was a committee of three—two were for electric light and one for gas. If that was the reason of the delay he hoped the town would not be kept waiting. Councillor G. Mowll said it was no such thing. They had asked the gas company and the electric light company for prices, and were awaiting them.

Huddersfield.—At the meeting of the Town Council the Electric Lighting Committee recommended that wirings and fittings for any person requiring electrical energy be supplied, providing the owner of the property undertook to repay the cost by annual payments with interest; but the recommendation was referred back in order that the committee might again consider the law relating to the borrowing of the necessary money. Alderman Calvert, the chairman of the Electric Lighting Committee, stated that for the half-year ended June 30 last there had been a deficiency in revenue of £116. 11s. 9d., as compared with £624. 0s. 11d. in the corresponding half of last year.

Brussels International Exhibition.—It is hoped that electrical engineers and manufacturers will readily respond to the invitation of Mr. James Dredge, executive commissioner for the British section of the Brussels International Exhibition of 1897, and co-operate heartily in the efforts that are being made to secure a fitting representation of the manufactures of this country. Firms who intend to exhibit should communicate with Mr. Dredge at once, as already a large part of the available space has been taken up by Belgian manufacturers, to say nothing of those from Germany, France, and the United States. Full information can be obtained from the offices of the British section at 35 and 36, Bedford-street, Strand.

Morecambe.—Mr. Parker, electrical engineer, attended at the meeting of the District Council and explained his scheme for lighting the district with electric light. He also produced plans of the system and of an electrical generating station to be erected upon the portion of Toddy Moss. Mr. Parker also produced estimate of the cost of construction of the works and report thereon. It was resolved that the sum of £26,000 be borrowed upon security of the general district rate, for the purpose of defraying the expenses of purchasing portion of the undertaking of the Morecambe Electric Light and Power Company, Limited, and that application be made

Digitized by Google

to the Local Government Board for their consent to the Council borrowing the said sum of £26,000.

New Publications.—Mr. Gisbert Kapp has just completed the translation into English of his work "Transformers for Single and Multiphase Currents," and Messrs. Whittaker and Co. will issue the same in a few days. A series of electrical engineering design sheets by the same author is also being issued in England by Messrs. Whittaker, from whom alone copies can be obtained. The same publishers have in the press a work upon "Central-Station Electricity Supply," by Mr. Albert Gay, chief engineer, Islington Central Station, and Mr. C. H. Yeaman, chief assistant engineer at the same station. The work will be included in the Specialist Series, and will be fully illustrated.

Leatherhead.—Some remarks were made at the meeting of the Urban District Council on the question of Mr. Dearle's notice of motion for the next meeting, in which he proposes that application be made for a provisional order authorising the Council to supply electricity for any public or private use within the area of the district. Dr. Davis expressed the opinion that they were sufficiently protected, and that no company could establish the system of electric lighting there unless the Council passed a resolution permitting it. He could not help thinking that they had better leave the matter alone, as it would mean a great expense. The subject then dropped, the clerk stating that it would come up for discussion at the next meeting.

Incandescent Lamp Reflector.—The National Reflector Syndicate, of 21, Bridge street, Manchester, have sent us one of their patent incandescent lamp reflectors. It is simply a circular disc of bright metal about 2½in. in diameter with a hole in the middle to allow it to be fitted on to the stem of the incandescent lamp. It clearly must add to the amount of effective light, but the addition of 20 per cent. which is claimed for it is certainly a very outside estimate. The writer intends to try it practically to-night on the lamp over his desk. Anyone else who wishes to do so can get the reflectors at 1½d. each if he buys a dozen, so it is not an expensive affair; but if the syndicate can manage to sell them by the thousand at that price they ought be in for a good thing.

Aberystwith.—At the meeting of the Town Council a letter was read from 45 inhabitants of Bridge-street applying for an additional electric lamp, which they suggested should be placed near the Bridge-street entrance to Gray's-inn-road. It was decided that the matter should be referred to the Public Lights Committee for consideration. The Public Lights Committee, of which Mr. D. C. Roberts is chairman, reported that they had very fully discussed the present system of lighting the town, and, pending enquiry respecting the rearrangements contemplated, recommended that the present system should be continued. The committee had also considered the question of extending the gas-lighting to Penparke, but passed no resolution. The report was adopted. During the past four quarters the Corporation have spent £700 for electric and gas lighting.

Kensington.—The report of the Works and Sanitary Committee presented at the Vestry meeting stated that during the month of July 17 miles 665 yards of new overhead wire had been fixed, three poles renewed, nine miles of wire removed, and one pole removed. The following notices and plans had been received from the undermentioned electric lighting companies relative to extensions of their mains in the parish: Notting Hill Electric Lighting Company: Kensington Park-gardens; House-to-House Electric Light Supply Company: Old Brompton-road Collingham-road, Scarsdale-villas, Allen-street, Kensington-road, North-row, Warwick-road, Philbeach-gardens, and Lexham-gardens. An application had also been received from the London Hydraulic Power Company for permission to lay a short extension of their mains in Drayton-gardens, and this was granted.

Dewsbury.—At the quarterly meeting of the Governors of the Technical School, the Electric Lighting Committee reported that they had held several meetings, and having the sanction of the governors had arranged for the lighting of the classrooms, school of art, corridors, staircases. The installation, as decided on June 24, was to consist of 166 lamps of 8 c.p., 93 of 16 c.p., four of 50 c.p, and one arc lamp, and it was agreed to ask Mr. Mitchell, the borough electrical engineer, through the Town Council, to draw up the specifications for tenders; but on July 14 the committee decided to withdraw this application, and Mr. Lee, the secretary, was instructed to take steps for drawing up specifications, and to advertise for tenders. At the next meeting 17 tenders from firms in various parts of the kingdom were read, and these were ultimately reduced to three. Ultimately that of Mr. Richmond Turner, of Dewsbury, was accepted.

Shoreditch.—After a somewhat vigorous discussion the Vestry have adopted the following regulations in respect to the Hydraulic Power Company: "(1) That in future the surveyor or the Works Committee shall not give permission to the Hydraulic Power Company to lay further mains or make any new connections, but in all cases the permission of the Vestry must be first obtained. (2) That £1 per annum way-leave be charged the company per 100 yards of main that may be laid in future with the Vestry's consent, and 10s. for each connection whether to mains laid or hereafter to be laid, including the connection to Nos. 70 and 71, Paul-street, application No. 1,865, referred by the Vestry to this committee, and subject to the above alterations, the same conditions as now embodied in the existing agreements to be also imposed. (3) That where electric mains have not yet been laid in any streets, the Hydraulic Power Company be not allowed to lay mains under the footways of such streets."

Aberdeen.—A recommendation has been made to the Gas and Electric Lighting Committee of the Town Council and to the Harbour Board to light the quays with electricity, at an estimated cost of £9,336. The Town Council decided at their last meeting to grant the use of an engine and dynamo to the Great North of Scotland Railway for the purpose of lighting Ballater Station by electricity on the occasion of the arrival of the Emperor and Empress of Russia *en route* for Balmoral. The company were to pay all expenses and £5 per day for hire. The Finance Committee reported that they had considered a letter from the general manager of the National Telephone Company expressing regret at the Council's decision in regard to the company's application for permission to lay the main routes of their wires underground, and suggesting an interview on the subject, and that they had resolved to recommend that a reply be sent to the effect that the Council were of opinion that no good result could be arrived by such an interview. The report was adopted.

Bradford.—According to the *Bradford Observer*, the Tramways Committee have not yet decided what system of traction to approve for the proposed new routes. Horse-cars are out of the question for either of the routes; there is the strongest possible objection to the use of steam-engines; the employment of petroleum is not suggested at all; and up to now there has been great confusion of opinion as to the relative cost and merits of the various electrical methods. The committees are giving very special attention to the subject of electric traction, and have been placed in possession of reports dealing with every system yet tested in any part of the world. They have a specific offer for the working of the new lines from the Simplex Electric Conduit Syndicate, Limited, who wish an entirely new system of theirs to be put to a practical test on these routes, on such terms as will at the same time suit their purposes and leave the Corporation to take possession of the routes for themselves at any time if municipalisation should be thought advisable. It is not likely, however, that the Council will be troubled with the consideration of this matter until some time after the provisional orders have been obtained.

Rockhampton (Queensland).—We have received a copy of the half-yearly report of the Rockhampton Gas and Coke Company, Limited, which contains some very interesting figures. The report states that the working expenses of the electrical department were somewhat less than the preceding half-year, while the returns were rather larger. The electrical operations showed a profit of £279. 7s. 2d, which had been appropriated towards the payment of the interest upon the company's debentures, amounting to £300, leaving a difference of £20. 12s 10d., represented in the debit balance of the profit and loss account of this section of the company's business. The following profit and loss account shows the receipts and expenditure for the six months ending June 30 last: Dr.—Generating electric current, £520. 0s 2d.: management, etc, £64 1s. 6d.; printing, £8. 8s.; interest, £300; stationery, £11. 8s. 3d.; insurance, £25. 12s. 6d; rates and taxes, £3. 10s 6d.; private arc maintenance, £13 6s. 1d.—total, £946. 7s. Cr.—Electric current sales, £825. 4s.; sundries, £12. 17s. 8d.; electric light fitting account, £27. 10s. 6d.; interest, £17. 10s.; rental on electric light fittings, £42. 12s.; balance, £20. 12s. 10d.—total, £946. 7s.

Leeds.—A dispute has arisen between the National Telephone Company and their Leeds workmen. On Saturday the local management intimated that they would require their outdoor servants to work an additional half-hour a day—in other words, 53 hours a week, instead of 50, as at present—in order to make the conditions of labour uniform throughout the country. As no additional pay was suggested the men declined to work the extra time, and on Monday morning none of them put in an appearance until the usual time—7.30 a.m. Thus defied, the local manager refused to allow them to start, and the men adjourned to the headquarters of the Gasworkers and General Labourers' Union to talk matters over with Mr. J. Smith, one of the officials of that body. Later in the day Mr. Smith and a co-official had an interview with the local managers of the company, and it was arranged that the men should return to work on the old conditions pending instructions from the head office of the company in London. In addition to declining to work the extra half-hour daily the men request that they shall be paid time and a quarter for overtime on ordinary days, and double time for Sunday labour. They also request a certain allowance for walking to work at places more than three miles away. Between 80 and 100 men in the city are affected by the dispute.

Bolton.—For some time past there has been a growing demand for the electric light, and the recent decision to adopt the Brighton system of payment is expected to give a very considerable impetus to the work of the department. The Gas and Electric Lighting Committee have recently been considering the advisability of extending the works and plant, and at a meeting held a few weeks ago it was decided to apply to the Local Government Board for permission to borrow £35,000 to meet the growing wants of the town. Since then the electrical engineer, Mr. Ellis, has got out particulars, and at the last meeting he submitted an estimate showing that £25,380 would be required to provide the additional buildings, boilers, engines, switchboard, mains, meters, etc., necessary to the development of the department. It was pointed out that £44,620 had already been expended, this being an excess of £4,260 over the amount (£40,000) sanctioned by the Local Government Board. To meet this, and also to cover the expenditure on the proposed extensions, the committee decided to request the Finance Committee to authorise them to make an application to the Local Government Board for power to borrow a further sum of £30,000. This will bring the total expenditure on the Corporation electricity undertaking to £70,000. At the same meeting the electrical engineer submitted designs for the new arc lamps proposed to be placed at each corner of the Town Hall-square, one of which was selected,

Digitized by Google

Stirling.—At a largely-attended meeting of ratepayers held recently a motion was passed unanimously requesting the Police Commissioners to carry into effect without delay the obligation entered into by them with the Board of Trade to introduce the electric light into the burgh, and at a meeting of the Police Commissioners, when the above resolution was submitted, Provost Kinross stated that there was no obligation resting upon the Commissioners to introduce the light, and it would, if carried out, simply mean a deliberate waste of public money. Exception was taken to this statement at the meeting, and since then a ratepayer has written to the Board of Trade calling attention to it, and asking an explanation of the position of matters. A reply has been received from the secretary, Mr. T. H. W. Pelham, stating that the order provides, *inter alia*, that the undertakers shall lay down mains in certain specified streets within a period of two years from the commencement of the order; that they shall apply electrical energy within the remainder of the area on certain specified conditions; and that if they make default in laying down mains in accordance with the provisions of the order, the Board of Trade may revoke the order. The order is dated 1895, and is scheduled under the Electric Lighting Orders Confirmation (No. 1) Act, 1895, 58 and 59 Vict., cap. 66.

Leamington.—At the meeting of the Town Council, the Watch, Lighting, and Fire Brigade Committee reported that the borough surveyor had submitted a report showing the comparative cost of various systems of lighting the Parade. The committee recommended that lamps, Sugg's 40 c.p., be put up in York-terrace, Lansdowne-place, and the lamp by Christ Church, with a view to adopting this system of lighting the Parade and Bath-street down to the railway bridges if it should prove satisfactory. Alderman Wackrill moved the adoption of the report, which he considered hardly said sufficient as to the gas-lighting of the Parade. Everyone would agree that it should be done better than at present. As to the electric light, they had received an offer which the committee had gone into fully, with the result that they considered the cost would be much greater than they felt justified in asking the ratepayers to furnish. The Council would probably like to know the relative cost of gas in comparison with the electric light. The company offered to supply 18 arc lamps, of 1,300 c.p., each to be replaced after 11 o'clock by two lights of 16 c.p. for the rest of the night. The cost would be £494. 3s. 4d., or if the large lights were kept on all night, £735. 6s. per annum. The difference in the cost of lighting by electric light and gas was from £494 to £207 per annum. The report was adopted.

Brighton.—The seashore electric tramroad seems to be meeting with a very hearty reception now it is completed. Mr. Magnus Volk writes to the *Sussex Daily News* as follows: "Will you allow me through your columns (as it is impossible for me to do personally) to thank the large number of residents and visitors for their kind wishes and congratulation upon the success of the Rottingdean electric railway. The problem as to its working is completely solved, and in the most satisfactory manner, any alterations as to speed and power being now simply a question of calculation. Many adverse circumstances during construction have made the last two years very trying ones, but I am amply repaid for my endeavours, though without the liberal help and support of my fellow directors (Mr. E. O. Blackley, Mr. J. J. Clark, and Mr. R. J. Pope) I must confess my own efforts would have been futile." The Lighting Committee have resolved that an electricity main be laid in Alexandra-villas at an estimated cost of £75, and that the public lamps in that street be lighted by electricity instead of gas. The letter from Mr. W. H. Tyler, requesting that additional lighting may be provided in the upper part of Stanford-avenue, was again considered at the last meeting of the committee, and it was resolved that two additional lamps be erected in Stanford-avenue. The letter from Mr. T. Dawes, requesting that public lighting may be provided in St. Andrew's-road, was again considered, and it was resolved that two lamps be erected in St Andrew's-road. The borough surveyor submitted a plan showing the lighting of Preston Park-avenue and it was resolved that an additional lamp be erected there. An application was submitted from the Technical Instruction Committee for permission for students from the York-place Technical School to visit the electricity generating station on December 19 next. It was resolved that the request be complied with. These proceedings were confirmed at the last meeting of the Town Council.

Catalogues.—We have received the catalogue and price-list of the voltmeters, ammeters, and measuring instruments of the Whitney Electrical Instrument Company. This company's works are in the United States and in Canada, but their agency on this side of the water is in the hands of the Stewart Electrical Syndicate, Limited, 103, New Oxford-street W.C. The meters cover both continuous and alternating current work, and it is claimed for the voltmeters and ammeters for alternating currents that their readings remain correct if the rate of frequency changes. The prices are quoted in dollars, not £ s. d., and there are code words provided for ordering instruments. Another agency of the Stewart Electrical Syndicate is the "Pioneer" arc lamp. This lamp is of the enclosed globe type, and it is claimed for it that it will burn 150 hours with one pair of carbons, and may be run either singly on 100 volt circuits or two in series on 200 volts. The makers suggest that these lamps are particularly adapted for street-lighting, since not only is there a saving in the cost of carbons, but also in the wages of trimmers.—The Standard Accumulator Company. 39, Victoria street, W., also send a catalogue of portable hand lamps, pocket accumulators, four-volt bicycle accumulators, cautery and lighting accumulators, etc. The illustrations are very clear, and full prices are given.—We have received from the General Electric Company, Limited, of London and Manchester, a copy of the supplement to their sixth edition telephone catalogue just issued. The first portion is devoted to prices, explanatory letterpress, and diagrams referring to their general intercommunication system and to accessories of the same, such as cable junction-boxes, etc. The special advantage which is claimed for this system is that the switch can be left in any position as last used and a call still be received. The second half of the pamphlet is devoted to the "Stanley" telephone, which has been brought out for ready connection to existing electric bell lines. Besides the ordinary wall combinations there is the commercial "Stanley" set and a combined telephone (transmitter and receiver), in the handle of which is a ringing and speaking key, enabling the ringing circuit to be switched out and the speaking circuit in or *vice versâ*, by a simple compression of the hand. The "Boudoir" and "Library" pattern instruments (the latter combined with a handsome two-bottle inkstand) are also fully illustrated.

Wimbledon.—The question whether the Council should apply to the Board of Trade for a provisional order in conection with the electric lighting scheme was discussed at the Urban District Council meeting. Mr. Donaldson said by getting a provisional order the Council would be able to keep the control of electric lighting in their own hands, but would it pledge them to go on with the scheme? The Clerk said no. Mr. Donaldson said he would move that a provisional order be applied for on the ground that if they did not do so they would practically leave the district at the mercy of anybody else who chose to apply. Mr. Olley seconded. Mr. Neller remarked that if a company had given notice that they intended to apply for an order, the Council would have to give some guarantee that they would go on with their scheme within a given period. He did not think they would obtain parliamentary powers for the sake of keeping everybody else out. The Clerk did not think they were bound to pledge themselves to a scheme before going for these powers. Mr. Fawcett said he had had some experience of the Board of Trade, and he knew that they would not grant a provisional order unless the Council showed them what they were going to do. The company would be sure to oppose their application, and if that was the case the matter would have to go before Parliament, and it would cost the town not less than £3,000 or £4,000. Even if the application was not opposed it would cost from £240 to £250, and the Board of Trade would give them a certain time in which to complete the work. If they were not going on with the scheme, would it be worth while to apply for the order? He thought it would be much better to let the company apply for their order, and make them insert such clauses as would protect them against that in regard to which they complained of the gas company. At least 80 per cent. of the ratepayers in his ward were opposed to electric lighting. It was a system of lighting that was quite in its infancy, and if they spent this money it was a great question whether it would not be entirely wasted. Mr. Williams said the weakest thing they could do would be to stand aside and let someone else create a monopoly. The science of electric lighting was in its infancy, it was true, but they did not know what improvements might take place and how it would be cheapened in the course of the next few years. Mr. Crickmay characterised the scheme as a speculative transaction from first to last, and said there was a very strong feeling in the public mind that it would result in loss. Still, if they had decided to adopt electric lighting, as business men they must apply for the necessary order. The Clerk, in answer to questions, explained that when the Council obtained their provisional order they would not be bound to go on with the work. He could not say what the cost of the order would be. The Council decided to apply for the order, Mr. Fawcett alone voting against the proposal.

Crewe.—A sub committee of the Town Council have been making enquiry into the question of electric tramways and their adaptation to the streets of Crewe. It appears that Mr. Sellon, a representative of the British Electric Traction (Pioneer) Company, Limited, attended a meeting of the committee and explained that his company were prepared to apply for an Act of Parliament or provisional order to construct a tramway in Crewe and to lay down and work the same provided that the Town Council and the property owners did not raise any opposition, and provided also that the tramway was an electric tramway, the motive power being derived from overhead wires. The sub-committee next caused enquiries to be made at Glasgow, Leeds, Bristol, Birmingham, Coventry, Blackpool, Hanley, Stoke, Walsall, and Hartlepool to obtain information as to the working of the tramway system in those boroughs. Every corporation applied to declared that the tramways in their respective towns were a great convenience to the town and to the public. The sub-committee said there was no doubt that the ideal tramway from the municipal standpoint was one constructed, maintained, and worked by the corporation. That was the opinion expressed by nearly all the corporations from whom the town clerk made enquiries. But however much some members of the committee might personally wish this plan to be adopted in Crewe, they were unanimously of opinion that at the present time such a scheme was practically impossible. By the erection of the sanatorium and technical school and other public works a large amount has been expended, and in face of this the committee did not think there was the slightest probability that the Corporation, or the ratepayers whom they represented, would sanction such a large capital expenditure (perhaps £50,000) as would be necessitated by laying down their own tramways, nor would they care to face the possibility of a loss on the working. That being so, there remained to be considered the question whether Crewe should remain without tramways or whether they should be laid down and worked by a company. The

Digitized by Google

committee were, therefore, of opinion that if a responsible company were prepared to lay down and work tramways that their offer should be accepted. The British Electric Traction (Pioneer) Company, the committee considered, was a substantial and respectable company. The route of the tramlines suggested by the chairman of the sub-committee (Councillor C. H. Pedley) included a line from the Cross Keys, Coppenhall, in the north, to the railway station in the south; from the end of Victoria-avenue in the west to the end of Hungerford-road in the east; with a branch line from Mill-street, by way of Oak-street, Wistaston-road, and Victoria-avenue to Merrill's-bridge and another from the borough boundary at Wistaston along Nantwich-road to the corner of Mill-street. The sub-committee have come to the conclusion that a system of tramways in Crewe is much needed, and would be of great advantage to the inhabitants; that it is extremely improbable that the Town Council or the ratepayers would sanction the laying down of a tramway by the Corporation; that if a respectable and responsible company will at their own expense, lay down and work a tramway, it will be better to accept their offer than to do without tramways until the indefinite future time when the Corporation would lay them down; that the system of electric traction by overhead wires causes little or no disfigurement of the streets. The committee suggest that the Corporation should express its general approval of the proposal of the company to lay down and work an electric tramway in Crewe, and ask for the draft of the provisional order. When the Council get this, the question of the route to be taken by the tramway, etc., will be considered.

PROVISIONAL PATENTS, 1896.

SEPTEMBER 14.

20261. Improvements in electric hoists or capstans. William Harding Scott, Gothic Works, Thorpe Hamlet, Norwich.

20323. Improvements in telephone apparatus. Walker Moseley, 104, Lyndhurst-grove, Camberwell, London.

20339. Improvements in or applicable to phonographs. The Edison-Bell Phonograph Corporation, Limited, and John Hayton Greenhill, 191, Fleet-street, London.

SEPTEMBER 15.

20354. Improvements in electrical couplings. John Henry Tucker, 16, Oozells-street Birmingham.

20378. Improvements in holding and supporting imitation candles in connection with electric light fittings. Gustav Byng, 73, St. Stephen's-road, Upton Park, London.

20416. Improvements in or relating to electric alarm bells and like apparatus applicable to cycles and other vehicles. Alfred Julius Boult, 116, Hatton-garden, London. (Paul Archat, France.)

20419. Improvements in electric railways. Hippolyte de Romanoff, 23, Coleman-street, London.

SEPTEMBER 16.

20467. Improvements in and relating to quick-break double-pole switches and double-pole fuses for use in the controlling and distributing of electric light and power circuits. Herbert Henry Branson Deane, 104, Colmore-row, Birmingham.

20505. An improvement in electrodes for secondary voltaic batteries. Harold Imray, 28, Southampton-buildings, Chancery-lane, London. (Ralph John Walter Grindle, France.) (Complete specification.)

20513. Improvements in electromotors especially applicable to motor carriages and other vehicles. John Vaughan-Sherrin, 77, Chancery-lane, London.

SEPTEMBER 17.

20539. Improvements in electrical apparatus for signalling to or from a railway train or locomotive. Robert Burn, Alfred Charles Brown, and Leonard George Tate, 196, Green-lanes, Finsbury Park, London.

20579. Nicol's electric time-handicap starter. William Nicol, 60, Queen Victoria street, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, February 17, 1896, being date of application in New Zealand.) (Complete specification.)

20600 Improvements in and relating to electrodes. James Albert Deuther, 77, Chancery-lane, London. (Complete specification.)

20601. Improvements in and relating to electric furnaces. James Albert Deuther, 77, Chancery-lane, London. (Complete specification.)

20604. Improvements in electrical resistances. William Morris Mordey, 46, Lincoln's-inn-fields, London.

SEPTEMBER 18.

20707. Improvements in coating tubes by electro-deposition. James Greenwood, 4, South-place, Finsbury, London.

SEPTEMBER 19.

20745. An improved method of actuating switches or other controlling gear placed on or below the surface of the roadway in an enclosed conduit or other system of electric traction. Robert Pasley Stevenson, 7, Duddingston-park, Portobello. (Edward Henry Blathwayt Tyler, South America.)

20778. Improvements in safety attachments or devices for preventing the falling of suspended wires, cables, or conductors used for the transmission of electricity. John Aldworth and Joshua Shaw, 6, Lord street, Liverpool.

20796 Improvements relating to electric railways. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Robert Lundell, United States.) (Complete specification.)

20805. Improvements in devices for protecting electric circuits and apparatus or instruments from injury by excessive electrical potential. Valere Alfred Fynn, 47, Lincoln's-inn fields, London.

SPECIFICATIONS PUBLISHED.

1894.

23825*. Arc lamps. Brockie. (Amended.)

1895.

8210*. Magnetic needles. Gisborne. (Amended.)

9144. Electric soldering apparatus. Binswanger and Ball. (Amended.)

13958. Trolley systems of electric propulsion and in apparatus therefor. New.

16569. Manufacture of electrodes for voltaic batteries. Epstein.

20071. Conduits for electric railways. Philippi.

22234. Means for protecting electrical and magnetic apparatus against the disturbing effects of electric railways passing in proximity thereto Siemens Bros. and Co., Limited. (Siemens and Halske.)

1896.

10127. Conductors and collectors for electric railways and tramways. Leigh. (Keithley.)

10698. Electric time alarum apparatus. Bird.

10817. Electric brakes for electrically-propelled vehicles. Devonshire. (Potter.)

12183. Conduits for electric railways and tramways. Cope.

13889. Electrical distribution. Oppenheimer.

14014. Electric cooking and frying or roasting apparatus. Dymond. (The Chemisch Elektrische Fabrik "Prometheus" Gesellschaft mit beschrankter Haftung.)

15966 Electric arc lamps. Leitner.

NOTES.

The North-East Engineers.—We have to acknowledge the receipt of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders.

Belgian Telegraphs.—The jubilee of the establishment of the telegraph in Belgium has been celebrated by a largely-attended meeting at the Palais des Académies. The Minister of Railways presided.

Society of Engineers.—A meeting of this society will be held at the Royal United Service Institution, Whitehall, next Monday (October 5), when a paper will be read on "Discharging and Storing Grain," by Mr. William G. Wales, A.M.I.C.E.

"Electric Power."—We learn with regret that the issue of *Electric Power* is to be discontinued. It was an American monthly magazine, established in 1889, and in the quality of its matter compared most favourably with a great many of its contemporaries.

Breakdown.—There was no performance of "The Sign of the Cross" at the new Brixton Theatre on Tuesday, owing, it is stated, to a failure in the electric lighting arrangements. The installation is a private one, with engines and dynamos in duplicate. The precise nature of the breakdown was not made known.

Block Signalling.—In company with most of the rest of the Press, we stated last week that the late Mr. John Warwick was the patentee of a system of block signalling. Mr. Warwick's patent appears to have been one for "arranging and combining apparatus for the purpose of indicating whether the light of a semaphore or other railway signal is or is not burning, such purpose being effected by means of a piece or pieces expanded by the heat of the light, and contracted when the light is put out," thereby making or breaking an electrical circuit which actuates mechanism for giving audible signals.

Electric Gas-Lighters.—It is one of the troubles of the Welsbach mantle that, if you are not particularly careful how you light the gas, you break it or blow it to pieces with the explosion. The task is beyond the power of the ordinary street lamplighter with his pole, but, of course, the problem can be avoided. The favourite way is to keep the gas always alight with a by-pass, with the result that it occasionally gets turned on at mid-day with the crook end of a walking-stick. In the South of France they have fallen back on electricity, the spark that ignites the gas being produced by an induction coil and a dry battery. Quite a quantity of gas lamps are said to be so lighted in Toulouse. There is, of course, nothing new in the idea.

Paris Exhibition (1900).—The *Bulletin* of the French Society of Civil Engineers opens with a "note" by Mr. C. Labro on the forthcoming Paris Exhibition of 1900. A great deal of space is given to the classification of exhibits, which, it appears, is not to be geographical, but according to the nature of the exhibit. Mr. Labro thinks very highly of it, apparently because, of 18 groups containing from two to eleven sub-classes, the group of "education" comes first and military and naval exhibits last. Electricity is number five, but as the arrangement is not one of merit and dignity in any way, it does not seem what there is to insist upon in the position of any one group. As for the sub-classes in Group III. we have such incongruous matters as printing, theatres, music, medicine and surgery, coins and medals, all brought together. It has apparently passed the wit of the compiler of the classification to find a descriptive title for this group.

Steam-Turbines.—Prof. J. H. Barr has contributed an article to *Cassier's Magazine* on the subject of steam-turbines. After some historical matter, including our very old friend, Hero of Alexandria, Mr. Barr refers to the ordinary cylinder steam-engine and the loss due to transfer of heat from the steam to the cylinder wall and *vice versâ*, the mitigation of which is the justification of the compound and triple expansion engines. Mr. Barr says the steam-turbine is entirely free from any loss corresponding to this. If "entirely" has any meaning, this is, to say the least, doubtful. The Parsons, Dow, and De Laval types of steam-turbine are briefly compared, but there are no tests made under precisely similar conditions. The conclusion, however, is that the steam-turbine is a form of engine that will have to be reckoned with in electric lighting work at no distant date.

Cable Interruptions.—From the official list of telegraphic cable interruptions published in the Berne *Journal Télégraphique* communication had not been re-established on September 25 over the following cables: Loanda and Benguela (failure September 13), Penang and Medan (September 7), Bahia and Rio de Janeiro (September 4), the Equadorian land lines (August 11), the Para-Maranham cable (August 6), the Salisbury and Umtali line (July 11), the Columbian (New Grenada) land lines (July 4), part of the Amazon Company's cable (May 4), the Trans-African line beyond Mazoe (March 11), and the Puerto Plata and Martinique cable, which dates its failure from last December. During the month there were five failures on Siberian lines: all were repaired within the day. Besides short interruptions on the Florida and Saigon and Bangkok land lines, the only other interruption noted is that of the Zanzibar and Mombassa cable from August 23 to September 5.

Herz Wave Telegraphy.—We last week referred to the remarks made by Mr. Preece on the subject of experiments made under the auspices of the Post Office on Mr. Marconi's method of transmitting telegraphic signals by means of Herz waves, the details of which, however, were not disclosed. At the finish of the British Association, Prof. Oliver Lodge invited the members of Section A to witness in his laboratory an experiment in which, at an hour's notice, his assistant had arranged apparatus to do an exactly similar thing. Prof. Lodge expressed some regret that the resources of the Government should be open to foreigners, instead of encouragement being given to workers in this country. It may be worth mentioning that one of the points of using the Herz waves for this work, rather than, say, an ordinary heliograph, is that not only are they invisible, but if experiments at Cambridge are to be depended on, such things as brick walls or a house or two in the way would be no obstacle to the transmission of signals.

Royal Photographic Society.—The division of the photographers into three groups is somewhat of a puzzle to outsiders, but the Royal Photographic Society still represents the original foundation. Its annual exhibition at the Royal Society of Painters in Water-Colours' Gallery in Pall-mall East, was opened on Monday, and will remain open until November. It is stated that the total number of pictures submitted to the Selection Committee was above 1,100; but of these, owing to more rigorous selection, 354 have been hung—or about 100 less than is usually the case. This reduction is the result of the aim of the committee to increase the value of the selection of a picture

Digitized by Google

for hanging by raising the standard of work required. On Saturday evening there was a soirée in the gallery, a very large number of members of the society and their friends being present, the company including Sir Trueman Wood, Prof. Hatton, and Messrs. A. L. Anderson, Scammell, Marchant, Hertslet, Debenham, etc. Besides the photographs, there was an exhibition of cameras and other apparatus, acetylene lantern burners, and a demonstration of the Röntgen radiations.

Midland Mining Engineers. — At the general meeting of the members of the Midland Institute of Mining, Civil, and Mechanical Engineers last Saturday, at Sheffield, Mr. G. B. Walker, president of the institute, occupied the chair and delivered an address on the education of mining engineers. The mining students of this country, he said, did not usually receive a satisfactory technical education. He submitted that a mining student should be trained in the art and practice of mining, physics, chemistry, geology, machine construction and drawing, steam and steam-engine, electrical engineering, surveying, and mining jurisprudence, and in each of these he should have a thorough, not a superficial grounding. All that is a good deal for a student; but what Mr. Walker really wants for him is "to begin with two years at a colliery" (time to forget all he learned at school), "three years at a technical college" (learn it again), "two years in a colliery underground again, and one year in a colliery office." "A youth with such a training would be certain to be turned out thoroughly competent, capable of eventually filling the highest posts." This confidence that education will do anything provided you only arrange the taking of it in a new and uncongenial way is very touching.

Evening Classes.—The advanced evening classes in science which have been arranged for the coming session at University College and King's College, London, were mentioned in these columns last week. The courses are to be of the same standard as the day courses, and admission will be confined to students who have already made some advance in the knowledge of the subjects. The following are the subjects and times of the classes at University College, Gower-street, W.C.: Mechanical engineering (Prof. Hudson Beare)—Mondays, 7.15-9.30 (commencing October 12); electrical engineering (Prof. Fleming)—Tuesdays, 7.15-9.30 (commencing October 13); practical chemistry (Mr. C. F. Cross)—Fridays, 7.15-9.30 (commencing November 1). At King's College, Strand, W.C., the classes are: Civil engineering (Prof. Robinson)—Mondays, 7-9 (commencing October 5); architecture (Prof. Banister Fletcher)—Mondays, 6-9; and Wednesdays, 7-9 (commencing Oct. 7); experimental and practical physics (Prof. Adams)—Mondays, 6-7; and Wednesdays, 7-9 (commencing October 5); and pure mathematics (Prof. Hudson)—Tuesdays, 7-9 (commencing October 6). Application to join any of the above classes should be made as soon as possible to the professors who will conduct the courses. The fee for each course is £1. 1s.

Electric Light in the Far North.—Some particulars have been given in the *Elektroteknisk Tidsskrift* as to the running of the wind-driven electric light installation that was fitted up on Dr. Nansen's exploring vessel, the "Fram." Windmill pumps are common objects on Norwegian timber ships, but the application of a similar method to charging accumulators on shipboard is somewhat of a novelty. Moreover, to take such an apparatus straight away to the Arctic Ocean is certainly trying it high. Nevertheless, it appears that the apparatus worked satisfactorily while the "Fram" was icebound, until in May of last year, owing partly to the wearing out of the gearing of the toothed wheel in the windmill which worked the dynamo, and partly to the fact that portions of the apparatus were required for making snowshoes and runners, the apparatus was dismantled. But up to that time advantage had been taken of every puff of wind to charge the accumulators, so that the electric light was always available when required. It is interesting to note that in the severe cold the accumulator cells froze, but the acid-blended ice proved an excellent electrolyte, and the frost did not interfere with the working. Of course, sufficient current was not available for the ordinary lighting, but an arc lamp run from the accumulator was used by Dr. Nansen when painting or photographing.

The Radiophone.—There is a report from America that Prof. Alexander Graham Bell is devoting his attention to the development of his radiophone with a view to making it a commercially practical instrument. The radiophone was devised nearly 20 years ago, and it will be remembered that the principle of it is to utilise a beam of reflected light for the transmission of sound between distant points. The transmitter is made up of a thin diaphragm, silvered at its back so as to make of it a reflecting mirror, and is connected with an ordinary speaking-tube, into which the operator talks as he would talk into the transmitter of a telephone. Against the diaphragm is projected a ray of light. If this is sunlight, it is received by a mirror and directed through a concentrating lens at whose focus is the transmitting diaphragm. The latter reflects the ray through a second lens, which makes the components of the ray of light again parallel, so that it may travel any distance without dispersion. At the receiving station there is a parabolic reflector, at the focus of which is fixed a selenium cell. The cell in turn is connected with a telephone circuit. The rhythmic deformations of the transmitter diaphragm produce a scattering of the usually parallel beam of light, with a consequent variation of its intensity when projected on the selenium of the receiver. Any resulting variation in the conductivity of the latter affects the telephone circuit.

Motorcarts. — When the third annual race for "automobile" vehicles from Paris to Marseilles and back, a total distance of 1,051 miles, was started last Thursday, 32 motorcarts put in an appearance, of which two had steam power, the rest using petroleum. It was an expert's opinion that not more than four or five of the vehicles would complete the journey to Marseilles and back, as in the majority the machinery was too complicated and delicate to stand the constant vibration inherent in the petroleum-motor system and the rough work to which they would be subjected in the long race. About the first thing done was to run over a man (man hurt). Next day a fallen tree was run into (cart hurt). On the third a dog in the way caused a capsize of a motorcart (rider bruised). Ultimately, 14 of the motorcarts got to Marseilles, so the expert's opinion will probably be out by a large percentage. The final is not to hand at the time of writing this note. In America, one of the features of the Rhode Island State Fair at Narragansett Park recently was a competition of horseless carriages or motor cycles on a trotting track. Of 12 entries, seven contestants started. Two of the vehicles were driven by electric motors and the others by gasoline. The fastest mile was made by the carriage of the Riker Electric Motor Company, of New York—two minutes 47½ seconds. On a second day's trial one of the Duryea motor carriages developed sufficient speed to hold second place, the Riker machine coming in first, and the Electric Carriage and Wagon Company's vehicle third. The time was 14 minutes 33 seconds for the five miles.

Light Railways.—Last week we noted that the Board of Trade would allow a month's delay this half-year in the date for the submission of schemes under the Light Railways Act. We have received a letter from Mr. Sidney Morse on the subject, pointing out that this month's grace applies to the preliminary advertisements which have to be made in the local papers as well as to the submission of the schemes to the Board and the county authorities. To make it quite clear, we may repeat that under the rules notice of intention to apply for an order must be published by advertisement in each of two consecutive weeks in November next in at least one local newspaper circulating in the area through which it is proposed to make the railway. The notice must describe generally the line of the railway, its termini, the lands proposed to be taken, and the gauge and motive power of the railway, and must be subscribed with the names of the promoters. It must also name a place where a plan and section of the proposed works—with a book of reference to the same—and a plan of the lands to be taken may be seen. Copies of the draft order, plans, book of reference, section, and estimate of cost of contract must be deposited by the promoters during the month of December with the clerk of the county council, and of every borough, district, and parish council through whose area the railway is proposed to be made, and also with the Board of Trade. Copies of the draft order must be deposited with the Treasury, the Board of Agriculture, the Postmaster-General, the Commissioners of Customs and Inland Revenue, the Admiralty, the War Office, the Office of Woods and Forests, and the Office of Works, and, in the case of proposed railways in Scotland, with the Secretary for Scotland. The fee payable by the promoters to the Board of Trade before lodging any application is fixed at £50.

Power Transmission in Spain.—We have before now called attention to the progress of electric lighting in Spain. The following is an interesting example of the utilisation of a distant water power. The generating station which supplies current to Gandia and Alcoy, in the province of Valencia, is situated at the foot of a range of hills about half-way between those two places. The power is derived from the River Serpio, which winds along the foot of the hills. Though the stream has a considerable fall, this is by no means concentrated at one point. Consequently it has been dammed, and a channel cut along the side of the hills, into which a portion of the stream is diverted. After running for about 1¼ miles, the difference in level between this channel and the original bed of the stream amounts to a little more than 100ft., and at this point the generating station is erected. This contains two horizontal turbines, the water coming to them from a reservoir above through cast-iron pipes. The 110-kilowatt Siemens alternators are directly coupled to the turbines. They are wound for a voltage of 6,500 at the terminals, with a frequency of 50 cycles a second. The switchboard contains the usual fittings for high-tension work and synchronising the alternators. The line is an overhead one of bare copper, with oil insulators carried on wooden posts. The same posts carry the telephone wires between the generating and distributing stations. Alcoy is about 22 miles off the generating station, and the line drop exceeds 14 per cent. of the voltage. The local authorities absolutely refuse to allow extra high-tension currents to come into the town, so the first transforming station is some little way out. Here five Siemens transformers take down the voltage to 2,000, at which pressure the current is conveyed by an overhead line to a second transforming station in the centre of the town. This is an insulated cable line. At the town station the current is further transformed down to about 115 volts for distribution for lighting purposes. There are some motors, but these are fed from the primary by transformers of their own. The arrangement at Gandia is similar to the one above described at Alcoy, but smaller, due allowance being, however, made for the fact that the distance of Gandia from the generating station is not so great, and hence the line drop is less.

Telegraphic Topics.—An anonymous correspondent in the *Times* has discovered an Indian grievance which, so far as we know, has escaped hitherto the notice of the congress Babus. It appears that an Indian telegraph clerk is permitted to be ignorant of all alphabets but the Roman, and for all the Administration cares might be as unable to tell the difference between Sanskrit and Arabic as an eminent lady novelist who writes nonsense about electricity. In India, the correspondent is told—he does not seem to have been there—" all native telegrams must be translated, and retranslated on arrival, or must be written in Roman letters." He apparently wants the Arabic alphabet used. It is not a nice one for telegraphic work, but it is used in Turkey and Persia for languages that are really as alien to it as the Urdu. The trouble probably is that the users of all the other Indian alphabets would immediately want them adopted also. The ground would at once be taken away for rejecting Hindi in the classical devanagari script or Burmese and Southern Indian telegrams in alphabets that look as though they were written with a circular punch. So that instead of one grievance there would be three, with a prospect of more to follow. A more practical matter for English readers is dealt with by another correspondent. It is, that if anyone "notifies to the Post Office his change of address, but does not specially notify it to the telegraph branch of that office, telegrams will not be sent to his new address, though letters will be. Surely, as the office for delivering telegrams is under the same roof as that for delivering letters, the public have a right to demand the common-sense proceeding—namely that one notification shall suffice for both letters and telegrams." It is a well-known law of nature that an official cannot do anything unless someone fills up a form, but the public might have been told that two forms were necessary.

Impressions of a Telephone Exchange.—A representative of the *Porcupine* has been to see the telephone girl in her stronghold at the Liverpool Telephone Exchange. Mr. Martin, the district manager, took him, so he was not afraid. Even without adopting the theory of some subscribers that the telephone young lady has really a mission to avenge the historic wrongs of womankind on a business and therefore masculine world, one might reasonably be alarmed at the prospect of having to understand and describe intelligentlly a telephonic switchboard. This is what the *Porcupine's* representative saw as far as he remembers it: "The girls were busily at work, the telephonic apparatus attached to their left ears by dainty ribbons, so as to enable them to have their hands perfectly free. The young ladies appeared to my mind to operate with the swiftness and regularity of machines. A lady inspector sits in all her glory in an armchair in the centre of the room, while her assistants walk up and down before the operating boards to see that perfect discipline and silence are maintained and that no private messages are sent by any member of the staff." The "dainty ribbons" is hardly a masculine touch; to the ordinary man the affair seems frankly hideous, but we shall continue to assume that the representative of the *Porcupine* belonged to the masculine sex. He was told that "each young lady has 66 subscribers to attend to, and

sometimes as many as 70, and that it took three weeks for a neophyte to learn her duties," but he thinks it would take as many months before she became thoroughly expert. He was much interested in the battery-room. Next, he says, "I went into an oblong office where, by an ingenious contrivance which I cannot profess to describe, every wire in the service can be tested. So wonderful is this process that by it any break or defect in the wires can be instantly localised, whether in the switchroom or outside, just by touching a certain spot." Only to think of it! Then he was taken upstairs and shown the cables. "A curious circumstance in connection with these cables is the fact that rats run along them. Even the cables that are slimmest in diameter prove no obstacle to the progress of the nimble rodent." (The rats go outside, not inside, like the current.) But "200ft. below them lies the street, and did they fall from their narrow and slippery bridge inevitably would they be dashed to pieces." The rats "are attracted by the pig-skin hooks from which the cables are suspended; in fact, to such a pitch had the depredations of these creatures risen that the telephone authorities were obliged to protect their hooks by a kind of circular saw." For some time past, it is satisfactory to know, the rats have entirely disappeared.

Institution of Electrical Engineers.—A small party of students of the Institution of Electrical Engineers has recently returned from a 10 days' tour in Switzerland, where they visited a number of places of interest. The party left London on the evening of Saturday, August 29, by the Hook of Holland route, and arrived at Bâle on the following evening. On the morning of the 31st the Bâle electric tramway was inspected, and in the afternoon the students went on to Neuhausen, where they saw the Falls of the Rhine. The next morning the party saw the wire-rope and electric power transmissions at Schaffhausen, and in the afternoon were shown over Sulzer Bros.' large engine works at Winterthur, where Mr. Sulzer himself very kindly welcomed the party. The next two days were spent at Zürich, where the central station and two electric tramway stations were inspected. Very interesting visits were also made to the works of Messrs. Brown, Boveri, and Co., the Maschinenfabrik Oerlikon, and Escher, Wyss, and Co. The students were also shown over the physical department of the Zürich Polytechnic, and saw the installation at the Tonhalle, where a battery of accumulators is charged during the daytime off the alternating supply mains by means of a motor-generator, and is used for lighting the concert hall by night. A Pollak rectifier was formerly used for this work, but was found to spark too much. The Dolder cable railway, worked by an electric motor run off a private lighting plant, was also visited. The next day (Friday) the party went on to Lucerne, and had an enjoyable steamboat trip on the lake. The Stanserhorn cable mountain railway, which is driven by electric motors, the electric power being transmitted from a water-power station near the foot, was ascended. Fortunately the day was very clear, and a splendid view was obtained from the top. On the Saturday the students proceeded to Geneva, stopping for a short time at Berne on the way, where the Mekarski compressed-air tramway was inspected. At Geneva three days were spent visiting the National Exhibition, the works of the Compagnie de l'Industrie Electrique (système Thury), the Mont Salève electric rack railway, and the electric light stations, including the new water-power two-phase station at Chèvres, on the Rhone, where 18,000 h.p. is eventually to be utilised. On Wednesday, September 9, the party left Geneva and went to Lausanne by the lake, and the next morning most of the party left Bâle for England after a most interesting and enjoyable trip. The letters of introduction from Dr. du Riche Preller, Mr. Steiger, Mr. Escher (the Swiss representative of the Zurich Incandescent Lamp Company), and the secretary of the Institution, with which the students were kindly furnished, enabled them to see a good deal in the short period to which their visit was limited, and they met with the greatest kindness and attention from the various engineers and others to whom those introductions were addressed.

Foreign Code Telegrams.—Under the regulations of the International Telegraph Convention, code words must not exceed 10 letters in length, and must be taken from one or more of eight languages admitted for the purpose. Moreover, from reasons comprehensible to all electricians, it is desirable that the words used in a code should be so selected that the alteration of a letter or two should not transform any given word into another with a totally different meaning. As some codes are very voluminous, it was difficult to obtain within the restriction of the regulations a sufficient number of selected words; hence words were adopted which were the occasion of disputes between the telegraph administrations and the public as to whether a given assemblage of letters was a legitimate "word" or not. It was therefore decided at the Telegraph Conference of 1890 (at Paris) that the International Bureau of the Telegraph Administrations at Berne should prepare and publish an official list, from which code words could be selected. This "Authorised Vocabulary," consisting of over 260,000 words, was issued at the end of 1895, and purported to be a collection of code words suitable for telegraphic purposes with all dangerously similar words eliminated. It proved, however, to be nothing of the sort, as it was found that a very large number of words were retained which might by very slight alteration be transformed into other words which were also to be found in the vocabulary. It is by Great Britain and its Colonies and dependencies that by far the greatest use of code telegrams is made, and consequently both the Post Office and the Director-General of Indian Telegraphs, as well as the representatives of the submarine telegraph companies, opposed at the Budapest conference of June last the compulsory use of the official vocabulary, and as a result it was decided that the authorised list of words should be added to; that certain proper names should be permitted to be used in a code sense; and that it should be a list, as far as possible, of all the available words in the Dutch, English, French, German, Italian, Portuguese, Spanish, and Latin languages, without any attempt to eliminate words unsuitable from telegraphic or other points of view. Code compilers will thus be left to make their own selection from the Berne vocabulary, as they have hitherto been expected to do from standard dictionaries. This is really the only sensible course to take short of leaving the public to hand in anything for transmission at their own risk. Even an International Board cannot know everything and provide for all needs, and therefore it is better to let the manufacture of codes remain a question of supply and demand. Moreover, existing codes represent a valuable property which should not be destroyed, and therefore the International Bureau asks chambers of commerce, compilers of codes, and all who desire to have the words of their codes inserted in the second edition of the vocabulary, to forward, before the end of the present year, one copy of their code to Berne. In the meantime the decision of the Paris conference of 1890, that the official vocabulary should be made compulsory for Europe from January 1, 1897, is rescinded, and when the conference meets in London, probably in 1901, it will decide at what date the use of the amended official vocabulary is to become compulsory.

Scientific Education.—The current of controversy in the *Times* on scientific education has been split into two branches—"Scientific Education in England and Germany," "Science in the Old Universities"—but as these both relate to the same thing, and the letters are mostly the work of the same people, we shall treat them as one. Mere induced effects produced elsewhere as a result of the main stream in the *Times* we must, in general, ignore. First, then, we have Sir James Kitson again, who expresses polite incredulity in Dr. Clifford Allbutt's pretty little tales. Sir James says that the assertion that there is "no career in chemistry" in this country is misleading; indeed, absolutely incorrect. His examples, however, relate to iron and steel, not to dye work, organic chemistry, electrolytic processes, or, indeed, nine-tenths of what one first thinks of in connection with applied chemistry. Dr. Clifford Allbutt replies and sticks to the authenticity of his tales. But he gives away his whole case when he adds, "those applications of science which we are discussing at present are but means to the end of so subduing the ruder powers of nature that men may be more free to converse with the ideas of ethics, philosophy, and great literature." First of all, it was, "We do teach it"; now, "We are employed in higher work." As no one found any fault with what Cambridge provided in the way of science teaching, Dr. Clifford Allbutt had better have let the subject alone. The great "Y"—still the only man worthy of large type—insists, in opposition to Sir Bernhard Samuelson, that what is done under "the Technical Instruction Act and the Customs and Excise Act grants" is not enough, and, moreover, is not the right thing. The latter is so true that the former proposition need not be considered here. Further, as against Dr. Clifford Allbutt, "Y" again presses home the question, "Can he say that natural science 'pays' at the older universities?" Till this is on a fair footing with other learning, "a distinct bribe is held out to all the rising talent of the day to follow another groove of intellectual training, and that groove, under present conditions, a somewhat narrow one, notwithstanding the fact that many great minds have been trained in it." Which is true in fact, but how far it is material to the issue may be disputed. "Chemical Manufacturer" again repeats that it is all the fault of the public. "Abroad, good chemists were available before chemical manufacturers wanted them." So apparently they tried them and found them useful. The argument is probably better than it looks. Sir Bernhard Samuelson defends the spending of the available money on popular and elementary scientific teaching on the ground that "the rating power under these (the Technical Education) Acts will be a dead letter till the ratepayers themselves have been educated to understand what higher technical education means, and its pecuniary value to the country." But what is going to happen while a new generation is growing up? Also Sir B. Samuelson says Sir James Kitson is too confident and under-rates the fierceness of the present struggle with other countries, and what it is likely to become in the immediate future. Mr. R. J. Friswell complains that there is only one manufacturing chemist amongst the members of the Royal Society, and he ceased active association with manufacture 23 years back. Surely this is a matter which has as little real influence on the question as the fact that was made so much of, that in Court and "noble" circles in Germany there is more readiness to be civil and polite to a scientific professor, who is quite harmless, than to a rich manufacturer, who might, if he were encouraged, become a serious rival in the social sphere.

Maidstone Technical School.—We have received the prospectus of the winter classes at the Maidstone Municipal Technical School. There are elementary and advanced classes in magnetism and electricity, and a class in practical electricity which is to cover such matters as the construction and calibration of electrical measuring instruments, switchboards, and regulating apparatus, the principles of electric light fitting, joint making, how to design an electric light installation, telegraphy and telephony, construction of instruments, testing for faults in lines and cables, etc. The electric installation at the school is available for the purpose of instruction. These three classes are under the care of Mr. W. A. Stevens, A.M.I.C.E. To celebrate the opening of the winter session there has been a conversazione at the school. According to the programme, there was a concert, but the local newspaper ignores that, presumably as below the dignity of technical education, and remarks that the proceedings "were for the greater part of a scientific character. They were well calculated to create an inkling after knowledge." After this, in the first half-dozen lines it might be imagined that the reporter would have some difficulty in keeping up to the same standard all through. Nevertheless, he manages it by devoting the whole of the rest of his account of the conversazione to a lecture by Mr. Stevens on the Röntgen radiations. Yet though the result is that Mr. Stevens's contribution to the conversazione gets 91 per cent. of the available space, that gentleman is not satisfied, and is believed when he read his lecture in print to have cast about and considered the proper way of blowing up the editor, reporter, and literary staff of our Maidstone contemporary. It is greatly to be regretted that, according to the reporter, Mr. Stevens "was unable to give a thoroughly practical demonstration with the 'X' rays, as he had not a sufficiently powerful induction coil at his disposal to produce so great a number of vibrations per second as was required. His instrument would only produce a spark 6in. long, whereas the operation required a spark 3ft. in extent." We cannot think that the managers are seriously to blame in not providing any means of procuring yard-long sparks, although it would have been certainly more exciting. Some people are never satisfied. The following are a few other gems selected from this report of what Mr. Stevens did not say: "In explaining the sources of light, Mr. Stevens said that the air we breathe is like a mass of jelly, and light was known to exist by a sharp luminous object on which the rays fall, then the ether vibrations are presented by the object on which the light falls; they take up the vibration of ether and then the light or reflection from them enters the eye, in which, by way of the nerves, the brain receives the sensation of light." What could be simpler? We are sorry to hear, however, that even a portion of the Maidstone air is as thick as jelly, although the inhabitants apparently select that portion for breathing—perhaps under the idea that it is nourishing. "The lecturer went on to explain the difference between the conception of the ear and eye. The eye, he said, was only capable of realising light to the extent of from 16,000 to 30,000 vibrations, while the ear had an extent of from 39,000 to 50,000 vibrations." And, finally, "the only reason why we could not see through a brick wall was because of the rays of vibration." But seriously, if even the most junior reporter doing his honest best and with his shorthand to help him makes such a glorious mess of it when he tackles an unfamiliar subject, what sort of notions must many of the general public get from a popular science lecture? Fortunately they never try to apply their misinformation.

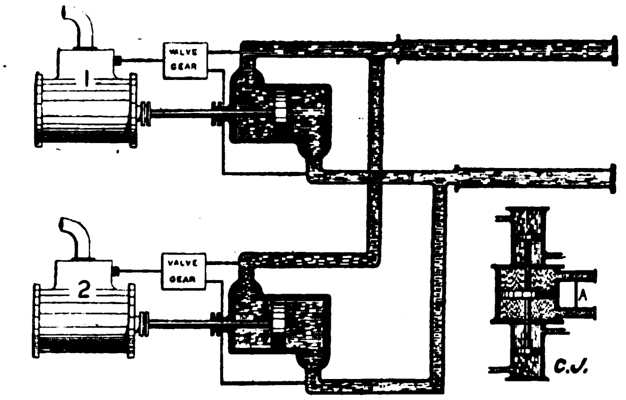
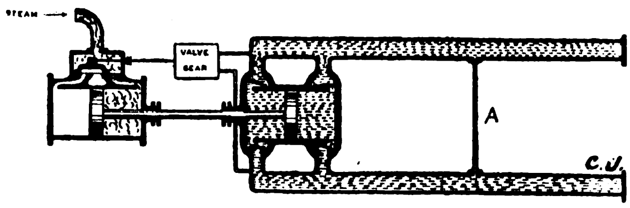
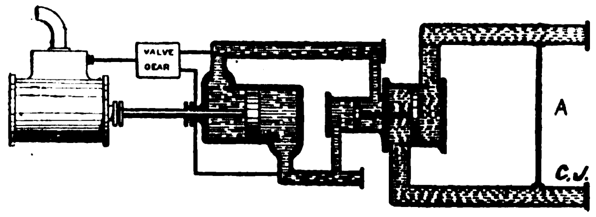
THE BRISTOL CENTRAL ELECTRIC LIGHTING STATION.*

BY J. R. BLAIKIE, ASSISTANT ELECTRICAL ENGINEER TO THE CORPORATION OF BRISTOL.

In the following description of the Bristol central lighting station the author proposes to deal solely with the principles as compared with other electric lighting stations, drawing attention to characteristic features of the present plant. There are in existence now about four types of lighting systems — viz., low-tension continuous; high-tension continuous; high-tension alternating; high-tension alternating polyphase. Combinations of two or more of these systems are frequently used, but one is usually sufficiently developed to characterise the station. Bristol belongs essentially to the high-tension alternating class. Before going further, it would perhaps be interesting to point out the *raison d'être* of these various systems. Hydraulic analogies will be correct enough for this purpose, and are extremely simple to follow.







Case I.—Low-tension continuous: The usual requirements of this system are, first, that there shall be a constant pressure maintained on the supply mains, and, second, that the speed of the machine shall be constant, as there would be a difficulty with the prime movers if this were not the case. In considering a pump, therefore, the pressure of the water must be kept to a standard, and the number of strokes per minute constant. The quantity of water delivered may vary; this can be met by varying the length of the stroke to suit the delivery demanded. In the diagram is shown a box containing such mechanism as will operate on the steam-valve to fulfil these conditions. The small pipe, A, connecting the mains represents a lamp. When such a flow as the area of the pipe will permit under the constant pressure passes the analogy is complete, and in the case of a lamp and an electric current the filament would be heated to a high temperature and emit light. It is obvious that by connecting in more small pipes between the mains the resistance to the flow is reduced and a larger quantity of water will pass. This necessitates a longer stroke of the pump, and consequently more work is done (the same pressure on the plunger acting through a greater distance.) In this case we can also store the energy by means of an accumulator, and the analogy still hold good. In order to serve all consumers alike, it is necessary to maintain this constant even pressure over all the supply mains. There is a difficulty in doing this; owing to the resistance the mains themselves offer to the flow the pressure would diminish a little at the more remote parts of the circuit. This difficulty can be obviated by having extra large mains; but these are very expensive. There is another way of satisfying the conditions, which is known as the high-tension system (Case II.). We now make our pump supply water at a pressure which is, say, 10 times too great for the lamp. This high-pressure water is taken to sub-stations and is used to drive water motors, which in their turn operate pumps designed to supply 10 times the quantity of water at one-tenth of the original pressure. These sub-stations can be placed at convenient points for secondary distribution. The high-tension or primary mains will therefore only have to carry a small quantity of water, and may be large enough to carry it for long distances without much loss of pressure. This completes Case II. It will be observed that all that is necessary to illustrate a lighted lamp is a small pipe with a flow of water through it. It does not matter which way the current flows, or even if it flows alternately in opposite directions, provided that the alternations or reversals are sufficiently rapid. The analogous hydraulic mechanism for the production of alternating flows simply consists of a pump without any valves, and a transformer, two cylinders of relative areas with pistons attached to a common piston rod. This is Case III., the high-tension alternating. In the diagram the high-pressure water is represented by long thin lines, and the low-tension by short thick strokes. The advantage of this simplicity is readily seen. There are disadvantages, however, which prevent it becoming universal. The energy cannot be stored, and it is not so well adapted for driving rotary motors which may be required for the supply of power to workshops. This system is consequently restricted to the supply over large areas (which necessitates high tension), and where the demand is likely to be for lighting only. A bold development of the high-tension alternating system is the fourth case, known as the polyphase or two-phase. Its object is to overcome the disadvantages of the former type with regard to motors. But this is beyond Bristol, or even the whole of the English practice at present, so it is unnecessary for the author to go into any further description. Before leaving hydraulic analogies, there are one or two requirements of an alternating station that can be aptly illustrated. When the quantity demanded is such that the pump has reached its full stroke, or full capacity, it becomes necessary to connect on one or several more to help it. On referring to the diagram it is clear that it would not do, with pumps having no valves, for one pump to be on the suction stroke when the other is delivering, while both are connected to the same main. If this were the case the water would simply flow between the two pumps, and not through the circuit of mains. Both pumps must deliver at exactly the same moment, or, in other words, run synchronously. Of course the two pumps may be running with different lengths of stroke, delivering different quantities, but the periods of delivery or suction must coincide. When once in phase or in step they tend to remain so, as the lagging pump will be driven by the leading one until it makes up the speed again. The flow passing between the two pumps to keep them in phase is called the synchronising current, and is obviously waste energy. It is therefore of the utmost importance that the motive power supplied to the pumps should be controlled in such a manner as to keep them in step with the smallest possible synchronising current. The method of ascertaining the condition of phase in two machines, running independently before they are connected, and finding the precise moment to make the connection, is very simple. Two transformers are connected as shown in the diagram. The high-pressure cylinder or primary of one is connected to the one pump, and the high-pressure cylinder of the other transformer to the other pump, in such a way that if the impulses from each pump tend to make the two high-pressure pistons approach or recede from each other, there will be no flow in the pipe, A. If, on the other hand, one piston recedes as the other approaches, there will be a flow

* Paper read before the Association of Municipal and County Engineers at Bristol.

Digitized by Google

in A. A, as before, represents a lamp, and as the lamp glows or remains dull the phase is discovered, and the connection is made just at the moment when it glows brightly. One step further reaches a characteristic of the Bristol station. There are, broadly speaking, two kinds of alternators. The one in use here is represented by a pump as shown, having rigid walls. This type is known by the feature of low self-induction. The other type, having high self-induction, could be represented by a pump having elastic walls. In the latter case (with elastic walls) a sudden flow from one to the other would tend to stretch the walls, and the piston of the lagging pump would not respond so quickly to the urging influence of the other. This is an advantage in some respects, as it prevents undue strains in the machines if they should get out of phase. On the other hand, it encourages an alternating interchange of current between the two machines, which may grow into a dangerous swing and so throw them out of step. It is therefore desirable that the pumps should have this expansive property just at the time when they are connected, and made rigid again when properly in phase. This is done in Bristol by means of choking coils. The equivalent in the pumps would be by making communication with two elastic bladders at either end of the cylinders, for the more or less uncertain time of making the connection, and cutting them off afterwards. With the aid of these preliminary remarks the author hopes to be able to make some of the excellent points in this installation more apparent.

Beginning with the generating plant all machines are direct driven, thus saving considerable space and eliminating the losses in transmission by ropes or belts. Driving direct means using high-speed engines, and we have what is generally accepted as the most satisfactory and efficient of this class—viz., the Willans and Robinson central-valve engine. All are compound and single acting; the high-pressure cylinder is in line with the low-pressure, tandem style. With the dynamos, or continuous-current machines, there are two lines of cylinders acting on two opposite cranks. With the alternators there are three lines, acting on three cranks at 120deg. Now we have seen the necessity of keeping the alternators in phase. That not only means keeping the speed of two or more engines exactly the same, but also each part of a revolution in various machines must be synchronous. The three-crank Willans engine is unique in conforming exactly with the required conditions. The three cranks at 120deg. keep the angular velocity constant, and further, owing to the tandem arrangement of the cylinders, the work done on each crank is the same, no matter what proportion of it is done by the high or low pressure cylinder. The engine is thus enabled to give a perfectly even turning moment when running at light load, which is most important for the process of synchronising. With other types of engine the angular velocity can be kept constant by using heavy flywheels, but these, of course, absorb power in themselves. Another disadvantage to the use of flywheels is that the speed of the incoming engine cannot be varied so rapidly to synchronise with the present running plant. There are several interesting features in the Willans engine that claim attention. The cranks run in a bath of castor-oil and water, which not only makes a very efficient means of lubrication, but is suitable for indefinite runs : a week or more, night and day, is no difficulty whatever. There are tubes provided in the bath for cooling purposes, and cold water may be circulated if necessary. The engine being single acting, all the bearings are in constant thrust, so the wear takes itself up automatically, and thus prevents knocking. For thermal principles and safety there is practically no cushioning in the cylinders; the momentum of the reciprocating parts is balanced by an air buffer on the up stroke; on the down-stroke some energy is taken from the flywheel, which is necessary in order to keep the connecting-rod bearings tight on the cranks. In engines as at Bristol, suitable for condensing, the exhaust steam from the low-pressure cylinder is transferred on the up-stroke to the under side of the piston, and opened to the vacuum on the next down-stroke, so that all work is done on the down-stroke, the essential principle of the engine. Particulars as to the number and capacity of the alternators will be found in the schedule annexed. The other generating plant consists of four dynamos (represented by pumps with valves), which supply a continuous current or flow. Two of these supply current for inducing the magnetic field in the alternators, and are called "exciters"; the other two "arc machines" supply the current for the street illumination by means of arc lamps. The principal reason that continuous current is preferred for arc lighting is because an arc formed between two carbon pencils with continuous current can be made to burn the top carbon in the form of a crater, and the lower one to a point. This formation reflects the light downwards, and so illuminates the more useful area. Steam is supplied at 125lb. pressure per square inch from a ring main, having valves inserted at suitable distances so that one portion may be cut out for repairs without interrupting the supply. The ring is fed by seven steel Lancashire boilers, which are arranged in two batteries of three and four on either side of the chimney. The chimney is 180ft. high, 9ft. 6in. internal diameter at the bottom. It is built in two shells, having a ventilating space in between. The boilers are fired by mechanical stokers of the coking type, made by Messrs. Vicars and Co. The coal is pushed on to the front of the fire, which causes the unburnt gases to pass over red-hot cinders and so ignite. With Welsh steam coal and this system of firing there is no smoke whatever. The coal is raised from the bunkers by means of an elevator and carried to the hoppers of each boiler by a conveyer, consequently there is no handling of the fuel to be done at all. The firemen have simply to regulate the mechanism, attend to the feed-water, and remove the ashes and clinker every few hours. After the steam has passed through the engines it is led away to the exhaust-main (which is also in a ring form with valves, as in the steam-ring). The exhaust-main has three outlets—one to the condensing plant, one to the atmosphere, controlled by a wheel valve, and the third to the atmosphere, controlled by an automatic back-pressure valve. In the normal condition of working the steam is condensed, and a vacuum of 25in. easily maintained. The condensing plant consists of one evaporator, to make up the water lost by small leakages; one large surface condenser; two centrifugal pumps, for circulating cold water from the river; and two air-pumps, for drawing off the condensed water. One pump of each sort is sufficient to do all the work at present; the others are spare plant.

Having dealt generally with the whole of the generating plant, we now come to the control and distribution of the electric current. The mains from all machines are brought up to the switchboard. Each machine has a separate panel, on which is mounted the necessary measuring instruments, switch, and safety fuses. From the board at the present time run 15 feeders to various parts of the city, some of them over two miles in length. Each feeder has its own instruments, etc., mounted on a separate panel. The arc-board is similarly provided with machine and circuit panels. The sub-stations are mostly under the pavements, and are brick-built chambers, 10ft. long, 6ft. wide, and 6ft. deep internally. They are spaced out to meet the requirements of each district, and are generally about 500 yards apart. The distributing cables run from sub-station to sub-station, thus making a network. The actual transformers are even simpler than the hydraulic model, for they have no moving part whatever. They consist of two coils of insulated wire wound on a laminated iron core. The ratio of the two pressures is proportional to the relative number of convolutions in each coil. As a matter of fact, by an arrangement known as the three-wire system, we are enabled to use double the pressure required for an ordinary lamp, and thus save considerably in the size of the mains. The cables are all lead-sheathed and armoured; they are laid in the ground in about 150-yard lengths, and beyond a covering of loose bricks require no further protection. It does sometimes happen that the "sanitary authority" in their enthusiasm for wood paving drive a steel drift clean through a cable, but in such cases it is questionable as to whether anything less than a 6in. armour plate would offer sufficient resistance. All the current is supplied by meter, and when consumed between the hours of 12 midnight and an hour before sundown it is supplied at a cheaper rate. This is contrived by means of a clock, which automatically

opens a small by-pass to the meter during these hours. In the schedule will be found particulars of all the plant.

In conclusion, the author desires to say that the aim of the foregoing paper is to make the subsequent visit to the works more interesting. With this object perhaps it is unnecessary to apologise for ignoring the well-beaten track of the cost of electric supply. With regard to the success of the undertaking, however, it will be sufficient to state that the Electrical Committee intend carrying out extensions during the next two years that will about double the present capacity of the station.

SCHEDULE.

Plant.	No.	Remarks.
Boilers	4	Steel Lancashire, with cross tubes, 28ft. by 8ft.
Boilers	3	Steel Lancashire, with cross tubes, 24ft. by 8ft.
Stoker engines	2	Vertical simple, driving stokers, &c.
Feed-pumps	2	Duplex direct-thrust type, built by Owen, each 4,000 gallons an hour.
Donkey pump	1	2,500 gallons per hour (type as before).
Feed heaters	2	Kirkaldy type with live steam.
Water softener	1	Howatson's.
Tanks	2	7,000 gallons each, in connection with softener.
Tank	1	3,760 gallons, for storing softened water.
Tank	1	790 gallons, for air-pump discharge.
Hot-tank	1	1,200 gallons, for feed-pump suction.
Oil-feed filter	1	Filter of coke and shavings between air-pump discharge tank and hot-tank with by-pass.
Cold-well	1	For circulating pumps, suction supplied from harbour through sluice-valve.
Engines	4	Willans I.I.I.S. type, compound, three-line, each 360 i.h.p., speed 350, coupled direct to alternators.
Engines	2	Willans G.G.G.S. type, compound, three-line, each 150 i.h.p., speed 465, coupled direct to alternators.
Engines	4	Willans G.G.S. type, compound, two-line, each i.h.p., speed 465, two coupled direct to exciters and two coupled direct to arc-lighters.
Evaporator	1	Capacity with live steam half ton per hour.
Condenser	1	30,000lb. exhaust steam per hour.
Air-pumps	2	Capacity 250 cubic feet per hour.
Circulating pumps	2	Capacity 2,800 gallons per minute through 15ft.
Alternators	4	Siemens 210-kilowatt 7,000 8-c.p. lamps, each coupled direct to Willans I.I.I.S. engines.
Alternators	2	Siemens 88-kilowatt 2,900 8-c.p. lamps, each coupled direct to Willans G.G.G.S. engines.
Exciters	2	Siemens 100-volt 50-kilowatt, coupled direct to Willans G.G.S. engines.
Arc-light dynamos	2	Siemens 100-volt 50-kilowatt, coupled direct to Willans G.G.S. engines.
Battery	1	A small storage battery of 54 cells in a room on the station is used for exciting the alternators on occasion, and for some of the station lights.
Switchboards	2	One consisting of six machine panels and 16 feeder panels, also synchronising panel; the other consists of two arc machine panels and eight arc circuit panels, also one exciting circuit panel.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 343.)

67. The result deduced in Art. 61 for the power in a circuit in which both E.M.F. and current obey the simple harmonic law is not of any importance as furnishing a practical method of measuring the power in an inductive circuit. Even if the simple harmonic law were followed in a given case, we should have to know the angle of lag, and the best method of determining this would, in fact, be to measure the power. The power measurement would thus precede the measurement of the angle of lag. The student must therefore guard against the fallacy that the result of Art. 61 furnishes us with a *practical* method of measuring power in an inductive circuit.

* Based on a series of evening lectures delivered at the University College, Liverpool.

Any method of measuring power which is to be of use in practice must be applicable to E.M.F.'s and currents of any shape whatever. In the next few articles we shall give an account of two of the most important methods of determining the power in an inductive circuit. A large number of methods have been invented from time to time, but by a process of selection only a few of these have survived to the present day.

68. When the circuit in which the power is to be measured is a non-inductive one the measurement presents no difficulty. For, as was shown in Art. 58, the true watts are in that case equal to the product of the volts and amperes, the power factor being unity. It is only where we have inductance in the circuit, and where consequently we have to reckon with an unknown power factor, that difficulties occur.

69. The first method which we shall describe for measuring power in an inductive circuit is that known as the *three-voltmeter* method. The arrangement of connections for this method is shown in Fig. 53, where A B denotes the

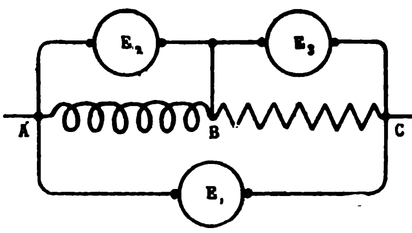

FIG. 53.

inductive circuit in which the power is to be measured, B C a non-inductive resistance of amount r connected in series with A B, and E_1, E_2, E_3 three voltmeters connected as shown. Let v_1, v_2, and v_3 denote the *instantaneous* values of the P.D.'s between A and C, A and B, and B and C respectively. Then we must have, at the instant considered,

$$v_1 = v_2 + v_3 \quad . \quad . \quad . \quad . \quad . \quad (a)$$

Next, the instantaneous power in A B is the instantaneous P.D. between its terminals—*i.e.*, v_2—multiplied by the instantaneous current. The latter, however, is the same as the instantaneous current in B C, which, since B C is a *non-inductive* resistance, is equal to $\frac{v_3}{r}$. We thus have

$$\text{instantaneous power in A B} = \frac{v_2 \cdot v_3}{r}.$$

But from the equation (a) above we find

$$v_1^2 = v_2^2 + 2\, v_2 v_3 + v_3^2,$$

whence $$v_2 v_3 = \tfrac{1}{2}\,(v_1^2 - v_2^2 - v_3^2).$$

Substituting this value for $v_2 v_3$ in the expression for the instantaneous power, we get

$$\text{instantaneous power in A B} = \frac{1}{2\,r}(v_1^2 - v_2^2 - v_3^2),$$

and hence

$$\text{mean power in A B} = \frac{1}{2\,r}\;(\text{mean } v_1^2 - \text{mean } v_2^2 - \text{mean } v_3^2).$$

Now if V_1, V_2, and V_3 denote the readings of the three voltmeters, we have $V_1^2 = \text{mean } v_1^2$, etc., so that

$$\text{mean power in A B} = \frac{1}{2\,r}\,(V_1^2 - V_2^2 - V_3^2),$$

so that the power is given in terms of the readings V_1, V_2, and V_3 of the three voltmeters, and the value r of the non-inductive resistance.

70. In deducing the above expression for the power in the inductive circuit, we have made no supposition regarding the shape of the E.M.F. and current waves. The reasoning is perfectly general, and will hold for any shape of wave.

Instead of using three voltmeters, a single voltmeter may be used for taking the three readings consecutively. But it is always advisable to use three instruments if these are available, as it is important that the three readings should be taken at the same instant.

The non-inductive resistance r should be so chosen that the reading V_3 is as nearly as possible equal to V_2.

Digitized by Google

On the whole, the three-voltmeter method of measuring power cannot be considered a thoroughly satisfactory one. It is in most cases difficult to get good results with it, and sometimes comparatively trifling errors in the readings may give rise to a serious error in the determination of the power. Again, in order to carry out the measurement under the best possible conditions, the resistance r must be made large enough to absorb more power than that which is taken by the inductive load under test. For, as mentioned above, V_2 and V_3 must be made as nearly equal as possible to secure the greatest accuracy, and since the power factor for r is unity, while that for A B is generally less than 1, it follows that r will absorb more power than A B. The introduction of the resistance r, therefore, altogether upsets the existing conditions of the circuit, and in order to restore these we must provide a source of higher E.M.F. (about double that required by A B). It is not always convenient to do this, and hence the three-voltmeter method is necessarily limited in its application.

71. The most generally useful method of measuring power in an inductive circuit is that involving the use of a *wattmeter*. A *wattmeter* is an electrodynamometer provided with two coils—a fixed coil of thick wire and a movable coil of fine wire. The fine-wire coil is connected in series with a large non-inductive resistance, so that the time-constant (Art. 35) of the fine-wire circuit is extremely small, and hence its impedance practically equal to its resistance (Art. 38); the current in the fine-wire circuit will under these conditions be practically in phase with the P.D. across its terminals, the angle of lag being extremely small.

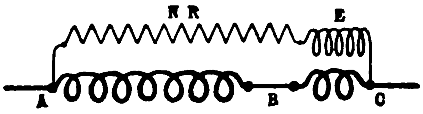

Fig. 54.

In Fig. 54 A B represents the inductive circuit in which the power is to be determined, B C the thick-wire coil of the wattmeter, E the fine-wire coil, connected in series with the non-inductive resistance N R. The couple acting on the fine-wire coil at any instant is proportional to the product of the currents through the two coils at that instant. Now the current through the fine-wire coil is, as stated above, in phase with the P.D. across A C, and is proportional to this P.D. Again, the current through the thick-wire coil B C is the same as the current through A B. Hence the couple acting on the fine-wire coil is proportional, at a given instant, to the instantaneous product of the P.D. across A C into the current through A C, and therefore the reading of the instrument, which depends on the mean value of the couple, will be proportional to the mean power. By multiplying the wattmeter reading by a certain constant, we at once obtain the power in A C.

Since the resistance of the thick-wire coil of the wattmeter is very low, the introduction of it into the circuit does not materially alter the conditions already existing in the circuit; in this respect, the wattmeter method of measuring power has a great advantage over the three-voltmeter one. The amount of power absorbed by the thick-wire coil is, it must be noted, included in the measurement. An allowance may be made for this, if necessary, by subtracting from the total power measured the product of the resistance of the thick-wire coil into the square of the current (which may be measured by an ammeter included in the circuit, outside A C *).

The constant of the wattmeter may be determined by using, in place of A B, a known non-inductive resistance, and measuring the current through it and the P.D. across its terminals. The product of these two quantities will give the power (Art. 58), and if the corresponding reading of the wattmeter be noted the constant of the instrument is at once determined.

* The ammeter might also be placed in the part of the circuit included between A and C; in this case, however, the amount of power absorbed by the ammeter must be added to that taken up by the thick-wire coil of the wattmeter.

72. At one time the wattmeter was not considered a satisfactory instrument. Readings obtained with it were found to be unreliable, and the instrument came to be looked upon with suspicion. The reason of this, however, lay in the faulty construction of the instrument, and a good modern wattmeter furnishes the best method of measuring the power in an inductive circuit. There are, in particular, two important points which should be carefully attended to in constructing a wattmeter. The first is that the time-constant of the instrument should be negligibly small, so that the current in the fine-wire circuit is for all practical purposes in phase with the P.D. at its terminals. The second point is that the supports of the coils, etc., should be constructed entirely of insulating material. If the instrument is provided with a case, the case should also be of insulating material. The presence of any large masses of metal in the neighbourhood of the wattmeter seriously affects its readings, owing to the currents which are induced in these masses by the alternating magnetic field due to the fixed wattmeter coil. These eddy currents react on the wattmeter and alter its reading. The student will understand this action better when we come to deal with electromagnetic repulsion phenomena, which will form the subject of the next few articles.

(To be continued.)

APPLIED ELECTRO-CHEMISTRY.*

BY JAMES SWINBURNE.

LECTURE II.

(Concluded from page 356.)

To sum up, in the electric and magnetic circuits the potential is cyclic. A unit charge or pole allowed to move in obedience to the force acting on it falls in potential continuously, and is not raised in potential at any point. The difference of potential is localised by the properties of the electric circuit itself, such as the resistance and the properties of the dielectric, leaving convection currents out of the question for the moment; and as there is no such thing as magnetic conductivity, the difference of magnetic potential is localised by the permeability and arrangement of the different parts of the magnetic circuit, and not directly by the position of the excitation. The engineer will say, "The lines of induction cut the wire of the electric circuit at certain places, and must generate the E.M.F. at those places, just as in a dynamo the E.M.F. is generated in the wires cutting the strong field. This is shown by the force on the wires there." The answer to this is that lines of induction are a mere conventional idea. Even following the idea up it will be found to be impossible to localise the cutting of the conductors by the lines. We can find two successive distributions, and we may assume that lines move or that a conductor moves past them and has a pressure induced in it. This is mere assumption though. All we can really deal with is the variation of the total induction interlinked with the electric circuit. No conceivable instrument will show where the lines cut the conductor. A voltmeter may be connected in shunt to a part of the conductor and give a reading. That voltmeter has leads to it, and the voltmeter and the leads form a local circuit, and any variation of the total induction through the local circuit gives a voltmeter reading. Carrying a charge on a proof plane and measuring the work done is the same thing. As to the force on the conductors of a dynamo, that depends only on the current. The force even then acts on the conductor carrying the current, not on the current. Similarly, in a magnetic circuit you cannot find any effect due to the location of the excitation.

This may at first seem a long digression from the question of the seat of the E.M.F. in a cell. But let us carry the idea of a cyclic potential to a cell with two terminals, connected by two pieces of wire to, say, a resistance which, in comparison with that of the rest of the circuit, we can consider infinite. Consider a unit quantity of electricity at the positive terminal of the cell. Suppose the cell gives one volt. Call the potential at the positive terminal anything, say 100. Follow the charge along the resistant part of the circuit. It does work and falls one volt, and gets to the negative terminal. The negative terminal is, therefore, at 99 volts. Seekers after the seat of the E.M.F. seem to assume that if the charge goes on through the cell to the positive terminal, the potential there will be 100 again; but it will only be 99. The potential of the terminals differs by a volt if considered as connected by the resistance, but they are at the same potential considered as connected through the cell. If the charge were raised one volt on its way through the

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

cell, the line integral of the electric force round the circuit would be zero, and the cell could do no external work.

A great deal of work has been done on contact differences of potential and allied subjects, but there is room for a fallacy. The difference of potential between A and B is defined as proportional to the work done by a unit charge of electricity going from A to B, but one cannot work with charges of electricity without something to carry them; and if A and B are conductors which may act chemically on the carrier, or on films of moisture or gases surrounding it, we are not really simply finding the difference of potential of A and B.

If the chemical pressure of the cell is higher or lower than the actual, so that the cell heats or cools on discharging, it might be said there must be something corresponding to glorified Peltier, Seebeck, or Thomson effects (it is difficult to remember which of these effects is which) between the metals and its electrolyte, and between the electrolytes, if there are two. But the algebraic sum of these differences taken through the cell must be zero, so the generation of heat, or its disappearance as a whole, must be regarded as chemical, or in some other way. Some day the theory of ions may be worked out on circuital principles. In the meantime I will go back to the usual way of discussing dissociation.

Dissociation.

Not so very long ago it was supposed that in aqueous solutions the water conducted the electricity, oxygen and hydrogen being given off in the nascent state. The nascent gases were then supposed to react on the substances in solution, oxidising and reducing them. Recently, however, as already mentioned, the theory of solutions and of electrolysis has made enormous strides, especially in Germany. The names of Hittorf, Ostwald, Arrhenius, van t'Hoff, and especially of Nernst, are more particularly identified with this development.

Too much space has been already given to the theory, or, rather, to one or two details of theory, to leave room for a long account of recent ideas of electrolytic dissociation. The theory is, that when a body is dissolved in a solvent, its molecules are moving as they would be in a gas. The mean free path of the molecules must, of course, be enormously smaller in a solution, and, I believe, that has been put forward somewhere as an objection to van t'Hoff's theory. Under certain assumptions, however, the figures work out right. If a small quantity of sugar, say, is dissolved in water, and the solution is separated from pure water by a diaphragm through which the sugar cannot be diffused, water will diffuse into the sugar side of the vessel. If it is closed water will come in, until a certain pressure is produced. This is the osmotic pressure, and it is found to depend on the number of molecules of sugar per cubic centimetre of liquid. Solutions with the same number of gramme equivalents per litre of different non-electrolytes give the same osmotic pressure, and the pressure corresponds to the pressure they would give as gases occupying the volume of the whole solution. Solutions containing the same number of gramme equivalents per litre also give the same vapour tension, and the same freezing point. Electrolytes, however, have higher osmotic pressures than Avogadro's law applied to solutions would give. This is explained by the dissociation or ionisation of salts in solution. Dissociation is a rather unfortunate term, as it is used for such splitting-up as that of ammonium chloride into ammonia and hydrochloric acid when heated, in which cases both the bodies found are ordinary substances. In electrolytic dissociation, for instance, salt splits into sodium and chlorine. The chlorine and sodium atoms are not as in free chlorine and metallic sodium, but are electrically charged, and give up their charges to the anode and cathode. Only part of the salt is dissociated, the proportion not dissociated or ionised depending on the strength of the solution. Thus, in a very strong solution very little of the salt is ionised. The term "ionised" is perhaps preferable to dissociated, as it suggests electrolytic dissociation as opposed to ordinary dissociation where the compound is not split into electro-negative and electro-positive radicles. As the solution is more and more diluted, the salt becomes more and more ionised. The electrical conductivity is due to the possibility of convection currents of the ions. The salt that is not ionised does not conduct. The current in the liquid consists of charged ions moving in different directions under the electric force. As the ions come against the electrodes they give up their charges, and are deposited as metals or given off as gas, as the case may be. The conductivity of a solution depends only on the number of free ions per cubic centimetre. A very strong solution has very few, so it conducts badly. As the solution is diluted the ionisation goes on more quickly than the dilution, so that though there is less of the elements of the compound in a cubic centimetre, the proportion ionised is so much greater that the total number of free ions per cubic centimetre is increased, and with it the conductivity. As dilution proceeds the ionisation no longer compensates for its effect, and we finally have a very dilute solution in which, though the ionisation is nearly complete, there are so few ions in a given volume that the liquid hardly conducts. Suppose, however, however, that we take a given quantity of the salt and dissolve it in a right prism of water of a given length with electrodes at the ends, and measure, not the conductivity, but the conductance from plate to plate; as the liquid is diluted the increase of cross-sectional area of the prism exactly counteracts the decrease of conductivity due to there being less of the elements per cubic centimetre, so that the increased ionisation tells independently. By this method, in fact, the combined charge-carrying capacity of all the free ions in a given quantity of salt is measured, and it increases with dilution as the ionisation goes on and tends towards a maximum at the point of complete ionisation, which exists at infinite dilution. By making a series of observations the molecular conductivity at infinite dilution—that is, under the condition of complete ionisation—is found, and the ionisation or the proportion of the ionised part to the whole of the salt at any dilution can be found from the conductivity. The results so obtained account perfectly for the osmotic pressure of an electrolyte being greater than that of a colloid or non-electrolyte. After ionisation the separate ions act as molecules, so that a dissolved electrolyte behaves as if there were an extra number of molecules added, corresponding to the ionisation. Electrolytes also lower the freezing points of solutions, and raise their boiling points more than corresponding gramme equivalents of non-electrolytes, but the results are quantitatively right when ionisation is taken into account.

The current in an electrolyte consists of a convection transfer of charges due to the ions moving in different directions under the electric force. They move at different rates under a given electric force. This is a point of some importance in practical work, as it controls the concentration of the solution in the immediate neighbourhood of the cathode and anode. The movement or migration of the ions must not be confounded with electric osmosis, which is a different phenomenon. Suppose we electrolyse a solution of hydrochloric acid. This consists of water, which is very slightly dissociated, and may therefore be regarded as not conducting at all; molecules of hydrochloric acid, which also do not conduct, for the hydrogen and chlorine have equal but opposite charges, and as they move together they cannot assist a convection current; and, finally, the solution consists of loose charged atoms of hydrogen and chlorine. They cannot be separated by diffusion as in ordinary cases of dissociation, for as soon as the faster-moving ions begin to diffuse into a new liquid their charges alter the potential of the liquids and thus the electric force comes into play, keeping back the fast and helping the slow and oppositely-charged ions. For every atomic equivalent of electricity that passes through the cell of dilute acid an atom of chlorine comes off at the anode and of hydrogen at the cathode. There are thus two atoms removed from the electrolyte by the passage of the electric charge of a single atom through the cell. If there were no movement of the ions, there would then be a hydrogen atom close to the anode and one of chlorine at the cathode. As soon as there is an excess of atoms of this sort there is a difference of potential between the sides of the electrolyte, and this causes the ions to move across. If they moved equally for every two atoms of chlorine and two of hydrogen deposited on the electrodes, there would be a movement of one atom of chlorine and one of hydrogen in opposite directions across any surface separating the electrodes, and the liquid in the neighbourhood of the electrodes would be equally impoverished as to hydrochloric acid. But suppose the hydrogen atoms move five times as fast as the chlorine for every six atoms of chlorine and six of hydrogen given off at the electrodes, five atoms of hydrogen and one atom of chlorine will pass an imaginary partition in opposite directions. The anode liquid will thus be impoverished by five molecules of hydrochloric acid, but the cathode solution will only lose one.

Space will not permit of a fuller account of electrolytic theory, and I must pass on to practical work, mentioning only a few processes.

The Ashcroft Process.

One of the most interesting of the more recent electrolytic processes is the Ashcroft method of treating the Broken Hill ores. As far as I know this process has never been fully described in print; in fact, I do not know that it has been described at all. The directors have very kindly given me permission to explain it as fully as I can, so I take the opportunity of doing so.

As is generally known, the Broken Hill mines contain enormous quantities, in fact, millions of tons of argentiferous sulphide of lead and zinc. Where this has been exposed to the weather for many thousands of years, the zinc and lead sulphides have been oxidised, and the zinc salts have been washed away. The lead and silver are then very easily dealt with metallurgically. The exposed and oxidised ore is nearly done now. Although enormous quantities of lead and silver have been taken from the Broken Hill mines, all that has been done so far is but a mere scratching of the surface compared with what there is still to do. The sulphide of lead and zinc is, however, a very troublesome ore to deal with. The zinc prevents its being treated as a lead ore, and the enormous mass has been regarded as valueless until some process for treating could be discovered. The lead and zinc sulphides are very intimately mixed, so that

Digitized by Google

concentration is exceedingly difficult. Of course, there have been endless schemes for the treatment of this ore, and probably every inventor in Australia has devoted some attention to the matter, but until the Ashcroft process was invented nothing very promising had been brought forward.

The Broken Hill ore may be taken to consist, roughly, of 30 per cent. of lead as sulphide, 30 per cent. of zinc as sulphide, and 25 to 30 ounces of silver to the ton. There is not much gangue.

In the Ashcroft process the ore is first ground—not too fine—and then roasted. This converts the zinc sulphide mainly into oxide. Of course the sulphide can be roasted till practically all the zinc is in the form of oxide, but it is most economical in this case not to roast so far. It will be said that this involves waste of zinc in the form of solution of sulphate, but the zinc at this stage is practically of no value. It pays better to allow a certain amount of zinc to be wasted rather than to go to the expense of roasting into oxide.

The roasted ore is then leached with a solution containing persalts of iron, and salts of zinc, sulphates, and chlorides. The oxide of zinc in the roasted ore is dissolved as sulphate or chloride, while the iron is precipitated as ferric hydrate. The ferric hydrate is apt to remain in its colloidal form, but the solution is heated and the iron thrown down. The solid matter is allowed to settle and the solution is run off. The solid matter contains all the lead and some of the silver, and some zinc. There is so little zinc, however, that it gives no trouble in smelting. The iron oxide is also required for smelting, and would have to have been added in any case.

The solution is led through tanks containing zinc plates or shavings to catch any silver. It then goes to electrolytic vats, and some of the zinc is taken out. The anodes in these vats are iron, so that iron goes into solution as ferrous chloride or sulphate. A diaphragm is used, to prevent the solution mixing. The mixing of the solutions would be fatal to the process, because iron would be deposited on the zinc. This would not only give zinc containing iron, but it would prevent the zinc coming down properly. It is by no means easy to produce a smooth, even deposit of zinc of any thickness; and as soon as a deposit begins to come down badly, it is very troublesome to get it right again. In order to prevent any chance of iron getting into the cathode chamber, the liquid on this side is kept at a slightly higher level, so that there is always a current through the diaphragm which prevents any trace of iron getting in. The liquid from the cathode chamber which has been deprived of some of its zinc, is led to a second set of vats in which more of the zinc is taken out. The solution is then led to the anode chamber first described, so as to take up iron in the ferrous stite. The ferrous solution is then led to the last vat, which has carbon anodes instead of iron. This converts the iron into ferric salts, and this solution, which contains ferric and zinc salts, is used for leaching the roasted ore. The process is thus cyclic.

Most people who have had experiences of leaching processes may be inclined to think that there must be difficulty in getting the iron completely thrown down by the roasted ore. The leaching, however, goes beautifully at once, and, after heating to deposit ferric oxide, there is no trace of iron to be found in the solution. It is necessary, of course, to have excess of zinc oxide, to make sure that all the iron is thrown down. Traces of aluminium and manganese salts may find their way into the solution, but that does not matter, as they cannot accumulate beyond a certain amount, as will be explained immediately.

The leached ore and oxide of iron contains a good deal of solution, so that a certain amount of zinc salts is taken with it. As the clear solution is separated from the sludge by decantation, and the sludge is still liquid enough to be run off into settling-tanks, it might be that it would pay to save the solution of zinc—but this is not the case. If the solution could be perfectly separated so that none was thrown away, and no new solution was added, the impurities would accumulate until they gave trouble in the depositing-vats. A certain proportion of the solution is therefore allowed to go off with the slimes, and the solution is made up with sea-water.

As explained already, the roasted ore contains zinc in the form of sulphates and of oxide. A basic sulphate may for the moment be regarded as a mixture of oxide and sulphate. The circulating system thus consists of a stream of solution which after leaving the leaching vats has its silver removed and then goes through cathode chambers, where about one-third of its zinc is taken. It then goes through anode chambers while it takes up the iron, which in the second set of anode chambers is converted into the ferric state, and the ferric salt is changed for zinc salt in the leaching.

It is only zinc in the form of oxide that is taken up in the ferric solution; that in the form of sulphate goes into the solution without any corresponding precipitation of iron. This zinc is useless, as it cannot be deposited in the tanks. All the zinc taken up as sulphate by simple solution is thus wasted. This is a very curious result, but a little consideration will show that it must be so. The zinc deposited in the vats is, of course, accurately in proportion to the iron dissolved. The vats must be arranged so that the iron anodes have twice the current of the carbon vats, otherwise there would be chlorine liberated, or ferrous salts in the leaching solution as the case might be. This result is easily secured by having two iron vats in series with one carbon cell. Suppose two gramme equivalents of zinc—that is to say, 130 grammes of zinc—are deposited in the cells with iron anodes, two gramme equivalents of iron—that is to say, 112 grammes—are dissolved as ferrous salt; in the next cell, with carbon anodes, the ferrous salt is raised to the ferric state, and another gramme equivalent of zinc is thrown down. For every three gramme equivalents of zinc we thus have two gramme equivalents of iron, and two gramme equivalents of ferric salt act on three gramme equivalents of zinc oxide in the leaching vats. The zinc deposited is, therefore, equivalent to the iron, and is thus the zinc that is taken up by action of the ferric salt on the oxide. If the same liquid always circulated without any being drawn off, the zinc would increase till the solution was saturated as regards zinc sulphate. The zinc sulphate is therefore drawn off to some extent with the slime after leaching. It may be utilised by other processes, but as far as this process goes it is a waste product. It still pays, however, not to trouble to roast the zinc sulphide completely into oxide.

Only about a third of the zinc is removed from the solution during one tour through the electrolysis-house. There has always been some difficulty in getting a good, smooth, dense deposit of zinc. It is very apt to come down in a spongy form, and in this case it is practically impossible to deposit it commercially. For that reason many people have advocated the use of alkaline solutions of zincates, such as the solution of zinc oxide in caustic soda. On the other hand, zinc sulphate will sometimes give very perfect deposits, and zinc sulphate was the electrolyte employed in the Edison electrolytic meter, where it seemed to work with almost perfect success. The deposition of zinc on a large scale from the sulphate has, however, generally given great trouble. In the Ashcroft process this trouble is overcome by the use of a solution containing basic sulphate and chloride of zinc. There is always excess of zinc oxide in the ore—that is to say, in leaching, the roasted ore and iron solution are so proportioned that there is more oxide than the iron can deal with. Though the basic salts of zinc are insoluble in water, they are fairly soluble in solutions of the corresponding neutral salts, so that the electrolyte really contains basic salts. This seems to make all the difference in the nature of the deposit. Even then the deposit is somewhat brittle. New wooden vats will sometimes add something to the solution which makes the deposit come down badly.

The vats are wooden tanks, and the cathodes are sheets of zinc suspended in cells which are dropped into the larger cells. The diaphragms are made of close texture canvas. The anodes are crude wrought iron. It is probable that crude pig iron will do, but cheap wrought iron is at present used. The circulation is arranged so that the current of liquid through the cathode chambers is quite distinct from the anode circulation; the liquid in the cathode chambers being kept at a little higher level as already explained, so as to make sure that no iron gets into the cathode cells. For the carbon electrodes either plates or rods of the same material as electric light carbons are used. This material is, of course, expensive, but it is not practicable to arrange for retort carbon, or any other cheap substitute, as, to get a reasonable output from a given area of a vat-house, the vats have to be deep. The circulation systems make it difficult to have sets of shallow vats one above the other. The carbon is attacked to some extent, but the corrosion is small, as there is plenty of chloride available. The oxidation has to be carried a trifle further than would suffice for the complete conversion of the ferrous into a ferric salt, so that a trace of chlorine or hypochlorite is formed. This oxidises any traces of ferrous salt that may not have come into contact with the anodes. It is most important to have no ferrous salt in the leaching vats, as they are not precipitated by zinc oxide, and would find their way into cathode vats, and spoil the deposit.

This process is the invention of Mr. Edgar A. Ashcroft, and is now owned by the Sulphide Corporation (Ashcroft's Process), Limited, who are commencing to work it in Australia. This company also owns a block of the Broken Hill mines, so that they have an almost unlimited supply of raw material to work upon. The process has already been worked on a manufacturing scale, and works are now being started in Australia and the United States.

Telegraphists' Strike.—A strike of the telegraph operators employed on the Canadian Pacific Railway has been ordered by the executive of their union. The majority of men working on the main line from St. John, New Brunswick, to Vancouver have left work, but on the Ontario lines the strike does not appear to be general, and things are better there than on any other part of the system. From Montreal to Quebec, and eastward to St. John and northward to Chalk River, the bulk of the operators are out. The strikers are badly organised and their funds are small, and the company's officials say they can get hundreds of operators from the United States, so that not much inconvenience is likely to be caused.

ELECTRICALLY-EQUIPPED RAILWAYS.

The additional information given by Mr. Cottrell in his paper on the "Liverpool Overhead Railway" to the Mechanical Section of the British Association is of considerable interest. It is somewhat difficult to state definitely where a light railway in contradistinction to a tramway begins, also where the light railway ends and the ordinary railway begins. Far too many, and we think for the most part absurd, comparisons have been made between what ought to be considered light railways electrically equipped in America and horse or electrically equipped tramways in England. You might just as well compare a poker and a pug dog. The same sort of comparison and attempted booming is going on with horseless motors. Syndicates and patentees whose aim is to make money are attempting to push into notoriety vehicles that have no more chance of general adoption than the old-fashioned war chariots of the ancient Britons. Horseless carriages will come, but they will not come with a great rush, and very great advances must be made in their construction before they can be deemed practical. We protest against all these misleading comparisons. Even in the case of the two electric railways in England—the one at Liverpool, the other in South London—they cannot be unreservedly compared with steam-equipped railways, because in the one case steam was altogether inadmissible, in the other only probably admissible. In both cases, in fact, electricity stood out far and away before every other kind of traction. We are glad, therefore, to see that in this paper no comparisons are made except between the two electrically-equipped railways. These, again, have little in common except that of electrical equipment. The London railway is almost entirely in a deep tunnel; the Liverpool, as its name shows, is overhead. Lessons have to be derived from each, for each supplies a unique case. Of course, similar or somewhat similar positions exist, and the success of these first attempts is leading to similar lines elsewhere. In Liverpool extensions have been and are being made, such extensions adding much to the utility of the original line. In London new lines as well as extensions, some connected with the original, some quite distinct, are being rapidly pushed on. Perhaps the most important experience to guide future workers is given in the two lines of statistics dealing with expenditure per train mile and revenue per train mile. Upon the ratio of these failure or success depends. At Liverpool the expenditure per train mile has been gradually increasing, a by no means good sign. Two years ago it was 13·10d., now it is 15·10d., or exactly 2d. per train mile increase. This may perhaps be accounted for in some simple manner, but we cannot from the statistics given see the reason. Certainly the number of passengers carried has increased about 100,000, and the mileage decreased about 1,400 miles, showing extra weight carried, but we doubt if this adds more than a small fraction of a penny to the mileage cost. The difference between the expenditure and revenue per train mile is 8·85d. now in favour of

Digitized by Google

revenue at Liverpool, while at London it is 10·34d. The expenditure per train mile in London is fairly constant, fluctuating perhaps about 0·5d. It can easily be seen that if such expenditure increases at a greater pace than revenue, the outlook is not so good as when the latter increases fastest. There is just one other point in these figures to which we might direct attention. At Liverpool the charge is by the zone system, and only first-class tickets are issued, the other class receiving no tickets; thus a saving is effected in printing and clerical work. The charge, too, is less than at London; yet the value per passenger at Liverpool is 1·97d., as against 1·72d. at London. As might have been expected in working new undertakings, improvements are being made which ought to add still more to successful working. The most important of these pointed out by Mr. Cottrell is the introduction of an ingenious form of roller bearings, the use of which it is expected will increase the carrying capacity of all trains by an additional carriage.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SOUTH SHIELDS ELECTRICAL SUPPLY STATION.

SIR,—In reference to your account of the above, I have a correction to make in respect of the statement as to planning and supervision of the buildings for which I hope you will find room

Your account says that I was clerk of works and also get out the bills of quantities in the first instance. To those who are closely connected with the building trade, such a statement as that would carry with it a suspicion that something was wrong.

The fact is that Mr. Jeckell had nothing to do with the designs, plans for, or superintendence of, the buildings and engine foundations. I throughout acted as architect to the building, and except a rough plan showing the relative positions of the various departments—such as any person intending to build could have made—I had no assistance whatever from Mr. Jeckell.

I enclose a similar communication which I made to a local paper, to which Mr. Jeckell has never replied, and the note added to same by the editor shows clearly where the blame lies. FRED. RENNOLDSON.

X RAYS.

At the meeting of the British Association in Liverpool this year a good deal of discussion took place regarding the various properties of Lenard rays, Becquerel rays, kathode rays, and Röntgen rays, which showed that great diversity of opinion still exists as to their theoretical and physical explanation. In the year 1893 Lenard made a remarkable series of experiments. He had a cylindrical tube with a kathode at one end which was either flat or concave, and he had the other end closed with a piece of thin aluminium foil. To this end of the tube was attached another tube which could be separately or concurrently exhausted with the first tube.

Lenard found that when the first tube was moderately exhausted, the kathodic rays in it were transmitted through the aluminium window into the second, and the distance to which they penetrated in the second tube before they became invisible through dispersion was greater the less the pressure of the air in the tube. When the second tube was exhausted for days, so that there was very little gas, if any, left in the tube, the rays were traced at a distance of more than a metre from the aluminium window. These Lenard rays, both in the first and second tube, are deflected by a magnet to about the same extent. Lenard himself believes that these rays are like light waves, or that they are, as he terms it, processes in the ether. The prevailing opinion amongst physicists in this country is that the kathodic rays in the first tube consist of molecules (gas or metal, or both) highly negatively charged. These impinging with great velocity on the aluminium window give rise to similar molecular discharge on the other side of the window, although the molecules themselves do not pass through the window.

Röntgen announced his discovery in the beginning of this year. His rays differ from the kathodic rays in not being deflected by a magnet, and apparently from ordinary light waves (1) in being transmitted by substances which are opaque to light; (2) in not being deflected unless to a small extent at a grazing incidence; (3) in not being refracted when allowed to pass through prism-shaped bodies; (4) in not being polarised; (5) in showing no diffraction.

The president of Section A, Prof. J. J. Thomson, in his presidential address ably and clearly showed that the absence of refraction and polarisation is no proof against the Röntgen rays being a form of light of very small wave-length. A curve from a paper by Helmholtz was shown. If the molecules of a substance have a natural period of vibration, and one only, the refractive index increases with the frequency of the light until the latter is equal to the frequency of the natural vibration of the substance. Then the refractive index diminishes, becomes less than unity, finally approaches unity, and becomes practically unity when the frequency of the vibration greatly exceeds the frequency of the natural vibration of the molecule.

Thus it was concluded that "the absence of refraction, instead of being in contradiction to the Röntgen rays, being a kind of light, is exactly what we should expect if the wave-length of the light were exceedingly small."

Similarly, for the absence of polarisation, tourmaline is fine-grained enough to polarise ordinary light, but it may be necessary to have a polariser of a much finer structure before we can get evidence of polarisation in Röntgen rays.

Lenard restated his views to the section, and adheres to the belief that both the Lenard and Röntgen rays are forms of light or that they are rays due to a disturbance in the ether. Sir George Stokes supposed that kathode rays on one side of the aluminium window gave rise to kathode rays on the other side of it by a process analogous to that of electrolysing copper sulphate with copper electrodes and inserting a copper plate between the electrodes. Copper ions come up to the plate on one side and leave it on the other, but do not pass through it. Similarly he supposed that kathode rays, which are negatively charged material particles, perhaps of gas, but equally probably of disintegrated electrode, strike the aluminium on one side, and the violence of the impact gives rise to a projection of molecules from the other side of the window. These projected particles on the other side of the window might have greater or less velocity than the original kathodic stream. Lenard objected to this explanation inasmuch as the deflectability of the kathode rays by a magnet is unaffected by the window. They are equally deflected in the vacuum tube and outside it.

The Röntgen rays Sir George Stokes was disposed to believe to be a sudden and non-periodic disturbance of the ether, either longitudinal or transverse to the direction of its propagation, the disturbance being repeated at each impact of a molecule against the surface from which the Röntgen rays emanate. On this supposition of a non-periodic disturbance there would be no diffraction, as a succession of the timed impulses is necessary for such phenomena. The same supposition would account for diffusion and luminosity in a turbid medium—such as air at ordinary pressure.

The following are some of the properties and effects of the Röntgen rays which were specially brought to the notice of the section: Thomson and Rutherford found that a gas while transmitting Röntgen rays is a conductor of electricity. The conductivity is destroyed if a current of electricity is sent through the Röntgenised gas. The strength of the current through gas exposed to Röntgen rays is, if small, proportional to the E.M.F.; but as the E.M.F. is

Digitized by Google

increased the current is not nearly increased in the same proportion, but tends to a value where it is almost constant and independent of the E.M.F.—that is, the current destroys and the rays produce the structure which gives conductivity to the gas, and a steady state is finally reached in which the rate of destruction by the current is equal to the rate of production by the rays. The conductivity under the Röntgen rays varies greatly from one gas to another. The vapour of mercury, which under ordinary circumstances is a good insulator, was found to be one of the best conductors.

Rücker and Watson noticed while experimenting on the transparency of glass and porcelain to the Röntgen rays that if a vacuum tube ceases to give Röntgen rays by reason of its resistance becoming too low, on coating the outside with tinfoil the rays appeared again. If the resistance is too high, heating the tube is the best remedy, as is well known. Trouton found that the duration of the Röntgen radiation at each spark varied from $\frac{1}{800}$th to $\frac{1}{10000}$th of a second. Thompson described some experiments with a Crookes tube, and various screens including aluminium of different thicknesses, and a mica plate covered with fluorescent material. In one set of experiments he used a concave kathode and a flat anode set at an angle of 45deg. to the axis of the anode. The rays from the kathode were reflected from the anode and produced shadows of two wires in their path. These rays on emergence from the tube still gave the shadows of the wire, but while the rays in the tube could be deflected by a magnet those outside could not be deflected. He found that arc light could send radiation through pinewood, but not through aluminium, which would cast a shadow of an obstacle on a photographic plate. Calcium sulphide gives off radiation even after retention in a dark room for six weeks. Cathode rays falling on uranium give rise to a more intense radiation of Röntgen rays than when they fall on platinum. The Becquerel rays, rays given off by fluorescent substances, especially uranium salts, after exposure to light, pass through aluminium and other opaque bodies so as to give photographs like Röntgen rays; discharge electrified bodies more readily than Röntgen rays; possess various degrees of refrangibility; can be reflected and polarised, and hence unquestionably are light. X.

ELECTRIC GLOW LAMP TESTS.*

BY WILLIAM HENRY PREECE, C.B., F.R.S., ETC.

(Continued from page 349.)

INSTALLATION TESTS.

In the case of Experiments 2 and 4, the lamps were rigidly mounted in suitable holders upon a stout shelf, fixed to a massive wall, so that no undue vibration should tend to shorten their life. The first group tried comprised two 8-c.p. lamps and two 16-c.p. lamps, as received from each of the firms mentioned against Experiment 2 in the above list, while a second batch of lamps comprised one 16-c.p. and one 8-c.p., as supplied by each firm named against Experiment 4. Two circuits were formed—one for 100-volt and one for 105-volt lamps, on identically the same system as that described for the continuous lighting tests. The illuminating power and current of each lamp at its normal voltage were taken before the trials commenced. Daily electrical measurements were made of each pair of lamps during the trial, and at the conclusion of the trial the existing lamps were again photometrically and electrically examined. If a lamp broke within the allotted 1,000 hours' run, it was immediately replaced by another of the same make and kind of known efficiency. Hence, in the two following schedules, lettered respectively C and D, the number of lamp corresponds to the first, second, third, fourth, etc., lamp installed. The so-called economical or high-efficiency lamps evidently suffered more than those of about 3¾ watts per candle. In some cases the life was less than that of the same sort of lamps in the continuous lighting tests, while in other cases no difference was observable. Of seven economical lamps supplied by one firm, five of the filaments broke within 1,056½ hours. Schedules C and D also show the life of each lamp, the current at start and finish, and the candle-power of those lamps burning at the conclusion of the trial. The longest run was 1,056½ hours and the shortest 23¾ hours. Omitting these numbers and others below 100, the average life of eight 16-c.p. 105-volt lamps was 463·47 hours, and of three 8-c.p. 100-volt lamps 556 hours. Schedules C and C_1 include the same kind of lamps as those bracketed against Experiments 1 and 2 in the preceding list, and Schedule D embraces lamps similar to those named in the same list opposite Experiments 3 and 4.

* Paper read before the British Association at Liverpool.

EXPERIMENT 5.—BREAKING VOLTAGE.

Having obtained a fairly good knowledge of the efficiency and durability of various glow lamps, under conditions of constant illumination and intermittent lighting, I next attempted to determine a quick and ready way of satisfactorily judging the quality of lamps. To obtain this end the voltage of several of the lamps already referred to was gradually run up for each lamp singly at a uniform rate until the filaments broke. At the moment of rupture the voltage, current, and time of running up were noted in each case. Before increasing the normal voltage, the current of every lamp was carefully measured, and the resistance (hot) afterwards calculated. In later trials the resistance (cold) was also found. The following table (1) gives full particulars of the average breaking voltage of lamps supplied by some of the firms before mentioned. It also shows the average current, resistance (hot), time of running up, and the difference in volts, amperes, watts, and the resistance (hot) between the normal requirements of the particular lamps and their breaking voltage. The four mean factors alluded to at breaking point are diagrammatically represented after the table of results. A suitable gearing controlled the motion of a falling electrode of copper as it gradually dropped through a column of very weak dilute sulphuric acid, which, on a 350-volt circuit, allowed the pressure of the lamp to be slowly raised to the breaking point. One assistant noted the volts and manipulated a chronograph, while another recorded the current at moment of collapse. Several lamps of like voltage and candle-power were obtained from various firms, and had their filaments broken in this manner. The average breaking voltage of the filaments was found to be 230.

EXPERIMENT 6.—THREE-FOURTHS OF BREAKING VOLTAGE.

Another series of tests were carried out in the same way as Experiment 5, except that the lamps were tested electrically and photometrically after, as well as before, being subjected to a high voltage. The object was to find what would be the effect on the electrical efficiency, candle-power, and the resistance of the same kind of lamps, when slowly raised from normal pressure to three-fourths of their mean breaking voltage. It is interesting to notice in Table 2 below that the candle-power is found to be rather more after the filaments have been raised to a high temperature and retested at the initial pressure.

From the trials of the numerous lamps that have been supplied to the Post Office, Table 3 has been calculated, showing their behaviour before and after being raised to three-quarters of their breaking voltage. They have been arranged in order of their initial efficiencies, and the percentage difference of candle-power and watts per candle-power before and after raising the voltage exhibited in tabular form. With the exception of the watts per candle-power in the case of the group of lamps of the initial efficiency 4 to 4·5, these differences are positive.

TABLE 3.—Table showing Behaviour of 16-c.p. Lamps (100 volts and 105 volts) before and after raising their voltage to 170.

Initial efficiency watts per C.P.	No. of tests.	Before raising voltage.		After raising voltage.		Mean differences per cent.	
		Mean C.P.	Mean watts per C.P.	Mean C.P.	Mean watts per C.P.	C.P.	Watts per C.P.
3·0-3 5	29	15·8	3·34	16·1	3·45	+ 1·9	+3·3
3 5-4·0	93	14·5	3·76	15·5	3·81	+ 6·9	+1·3
4·0-4·5	66	13 3	4·19	14·86	3·85	+11·7	-8·1
4·5 5·0	17	12·7	4·69	13·1	4·91	+ 3·1	+4·7

The foregoing results may be summed up thus:

1. The continuous lighting experiments show that the candle-power falls about 30 per cent. in 1,000 hours, and the watts per candle rise about 28 per cent. in the same time, as illustrated in the curves below (Sheet 1.), which connect time with candle-power (percentage) and watts per candle.

2. In installation work lamps of about 3¾ watts per candle, burning from seven to nine hours a day, behave as regards life and efficiency about the same as when given continuous illumination, but high-efficiency lamps deteriorate more quickly.

3. That good 100 or 105 volt 16-c.p. lamps, taking 3¾ watts per candle, should stand a gradual increase of pressure of direct current up to 225 or 230 volts (now made 210) in 3½ minutes before the filament breaks; that when slowly and regularly raised in 2½ minutes to, say, 170 volts—that is, approximately three-fourths of the mean breaking voltage previously alluded to—and afterwards retested at ordinary voltage, the candle-power should not be less than 14·4 nor

higher than 17·6, while the watts per candle should not exceed 4.

Evidently, in ordinary lighting, the candle-power of each lamp gradually drops and the watts per candle rise; but when the pressure is raised in a short time to three-fourths of the breaking voltage the candle-power increases, and so also does the current, but the first more rapidly than the second, hence the watts per candle should not exceed four for lamps of 3¾ watts per candle after the increased pressure has been applied to the filaments. This is rather a curious fact, and seems to indicate that when the filament is raised to a temperature considerably above that of normal, it, if of good quality, undergoes a beneficial change, as if the sudden cooling, after being at an abnormal temperature, causes some molecular alteration, which not only lessens its diameter and resistance, but affects its emissivity. Under these conditions the temperature of the filament is increased, and thus produces a greater amount of light.

To ascertain the characteristic behaviour and actual cost of various lamps referred to in this paper I have selected a number indiscriminately and divided them into three groups according to their initial efficiency, thus:

1. Those taking from 2 to 3 watts per candle. Sheet 2. Group F.
2. ,, ,, ,, 3 to 4 ,, ,, ,, ,, ,, G.
3. ,, ,, over 4 to ,, ,, ,, ,, ,, H.

Group F included three lamps only. Group G 19 lamps, and Group H 14 lamps, and it was so arranged that these numbers were maintained throughout 1,000 hours by renewal of lamps whose initial efficiencies were within the limits specified for that particular group. Three tables have been calculated, giving at intervals of 100 hours the candle-power per lamp, the watts per candle per lamp, and the total number of lamps replaced, and the results are plotted upon Sheets 2 and 3. Sheet 2 connects time with the candle-power and watts per candle per lamp for each group, and the curves thereon correspond with the results tabulated below.

TABLE 4.—Table showing Candle-Power per Lamp, Watts per Candle per Lamp, and Time.

Lamps of Initial Efficiency = 2-3 Watts per Candle.

(*To be continued.*)

A DIRECT-READING WHEATSTONE BRIDGE.*

BY A. P. TROTTER.

In James Swinburne's "Practical Electrical Measurements" (1888), Major Cardew's "Lightning Conductor" bridge is described, and is followed by a modification arranged by Mr. Swinburne as "a simple bridge on an emergency, or for amateurs."

"An evenly-divided scale, divided into, say, 1,000 parts, is mounted as shown in Fig. 10. A uniform wire is stretched over it from the binding screw, E to N, returning by D and F to the other binding screw, H. . . . The points E, K, M, and H are fixed, because they are determined by the design of the apparatus. The problem is to find the points F and D, so that the bridge will read proportionally from M to K, and will read in ohms, or tenths, or hundredths." The mode of calibration is discussed at some length.

It is to be observed that, unlike the ordinary Kirchoff bridge, the ratio arms are H D and F D, not H F and F D. Part of the slide wire, G M, is proportional to the unknown resistance + the remainder of the slide wire. In no books to which I have access can I discover the inventor of this mode of using a Kirchoff bridge. In the old mode two readings were taken, one from each end of the scale, and a ratio was obtained from which the unknown resistance could be calculated. This is far too cumbersome for practical use. I assume that this very valuable mode is due to Major Cardew. Mr. Swinburne suggests that more than one pair of points, F and D, may be found for more than one ratio. The form of bridge which is the subject of the present paper is derived from this suggestion.

The first modification is that the wire is not in one continuous length, but is arranged as in Prof. Carey-Foster's mode of comparing two slide wires, and consists of two wires connected together at one end by a bar of negligible resistance. One of these wires constitutes the ratio arms, and the other is the slide wire. The former is concealed in the instrument. Ratio points are carefully found once for all, and branch wires are soldered at these points. Among other reasons for which the manufacture of this bridge has been placed in the hands of Messrs. Crompton and Co. is the value of the experience which that firm has acquired in accurate adjustments of this kind in the manufacture of potentiometers.

It does not appear, in Mr. Swinburne's book, that he recognised that if two separate wires and a low-resistance connecting piece be used, the zero of the scale of resistances on the slide wire is always to be found opposite the ratio point on the ratio wire. To take advantage of this disposition, the scale of the present bridge is made to slide. This is the second modification.

Ratio points 1 : 1, 1 : 5, 1 : 10, 1 : 20, and 1 : 100 are determined and the necessary branch wires are attached. The scale sliding in a groove is provided with a spring catch which holds it accurately in place, with the zero opposite to any desired ratio point. In order to avoid the idea of applying a ratio, the ratio

* Paper read before the British Association at Liverpool.

Digitized by Google

points are described as 2, 10, 20, 40, or 200 "ohms maximum reading," the scale being divided from 0 to 20. This constitutes the third modification. The fourth modification, arising immediately from the last, is the utilisation of the spring catch for making contact between the ratio branch wire and the galvanometer. A galvanometer wire runs by the side of the slide wire, as in the Crompton potentiometer, and contact is made by the spring catch between this wire and the ratio branch wire.

The following diagram (Fig. 2) shows the connections. The whole arrangement has been reversed, in order that the scale may read from left to right. The ratio wire is divided into two parts—a and b. The ratio is not a/b, but $(a+b)/b$. The slide wire is divided by the sliding contact into two parts—e and $c+d$. The portion d is a measure of the unknown resistance x. The portion c is beyond (to the left of) the zero of the scale, and is equal to b. Then

$$\frac{a+b}{b} = \frac{x+e+d+c}{c+d}.$$

But from the construction of the apparatus $e + c + d = a + b$, and that $b = c$,

$$\therefore \frac{a+b}{b} = \frac{x+a+b}{b+d},$$

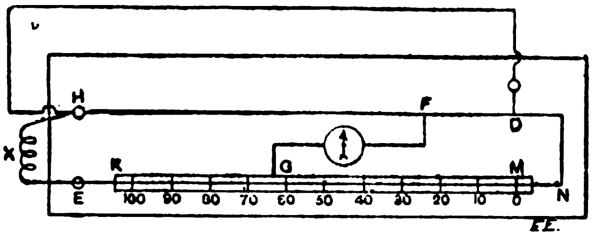

Fig. 1 (Fig. 10 reproduced from "Practical Electrical Measurements").

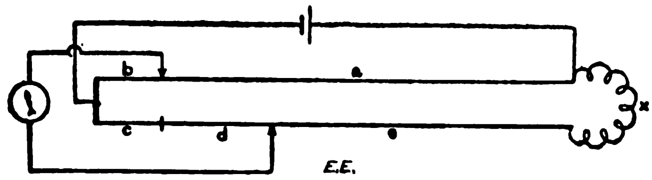

Fig 2.

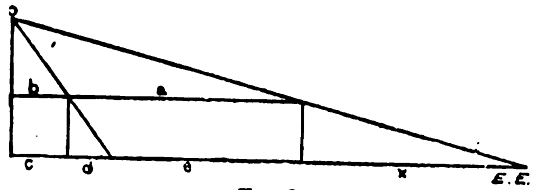

Fig. 3.

which cannot be true unless

$$\frac{a+b}{b} = \frac{x}{d},$$

or, graphically, let the line, $b\,a$, be divided into any two parts, b and a. Draw the line $c\,d\,e\,x$ parallel to $b\,a$. Complete the right-angled triangles, as shown in Fig. 3. Then $\frac{a+b}{b} = \frac{x+e+d+c}{d+c}$; and since $b = c$ and the triangles are similar, $\frac{a+b}{b} = \frac{x}{d}$. For a $\frac{1}{10}$ ratio, b is $\frac{1}{10}$ of the whole wire $a+b$, and a is $\frac{9}{10}$.

Nickel steel wire is used. The strength, hardness, freedom from corrosion, high resistance, and moderate temperature coefficient of this material make it peculiarly applicable for this purpose. It has been well tested, and has been found very suitable for potentiometers. The arrangement of the bridge as described allows the terminals to be very conveniently arranged.

The details of the instrument have been worked out by Mr. W. C. Fisher, of Messrs. Crompton and Co. The wires are 15in. long, and have a resistance of 2 ohms each. The whole instrument is 1ft. 5in. long, 2¼in. wide and 1¼in. thick, including terminals. For low resistances the scale is pulled half-way out; the maximum reading would be 2, but the two projects beyond the limits of the slider, and the highest reading is 1 ohm. One division of the scale is equal to $\frac{1}{100}$, and this may be divided by the vernier. For high resistances the scale is pulled out 0·15in., and the highest reading would be 200 ohms. This, however, projects beyond the limits, and 198·5 ohms is the highest reading. One division of the scale is equal to 1 ohm, and may be divided by the vernier.

ON A COMPLETE APPARATUS FOR THE STUDY OF THE PROPERTIES OF ELECTRIC WAVES *

BY JAGADIS CHUNDER BOSE, M.A. (CANTAB), D.SC. (LOND.), PROFESSOR OF PHYSICAL SCIENCE, PRESIDENCY COLLEGE, CALCUTTA.

The work of Herz and his eminent successors, both here and in the Continent, has opened out for study a new region of ethereal vibration, bridging over the gap that hitherto existed between the comparatively slow electric vibrations and the quick oscillations which give rise to radiant heat. In the vast range of possible ether vibrations we recognise only a few octaves by our senses; the rest are beyond our perception. Many unexpected properties of these little-known ether waves are now being gradually discovered. Confining our attention to the electric waves, we find that there are many important problems which may perhaps be better attacked with these comparatively slow ether vibrations, among which may be mentioned the determination of the indices of refraction of various substances which are opaque to visible light, but are transparent to the electric ray; the relation between the dielectric constant and the refractive index when the rates of oscillation are made comparable in the two determinations—the variation of the index with the frequencies of vibration. Then there are the phenomena of double refraction, polarisation, and the magnetic rotation of the electric ray, the determination of the wave-length, and other problems of a similar nature. The fascination of the subject drew me to its study, though the investigations were rendered exceedingly difficult in India from want of facility for making the necessary instruments. I ultimately succeeded in constructing a few instruments, with which I was able to obtain the values of the indices of refraction of various substances for electric waves, the wave-length of electric radiation, and to demonstrate the phenomena of double refraction and polarisation of the electric rays. Before you is the simplified apparatus with which many of the properties of electromagnetic radiation may be studied. This is a duplicate made by Messrs. Elliott Bros. of the somewhat rudely-constructed apparatus which I brought from India. I also take this opportunity of thanking Mr. Bolton, F.R.A.S., of the Mathematical Instrument Department, Calcutta, for the divided circle in my apparatus. The following are the experiments which may be carried out with this apparatus: A.—Verification of the laws of reflection: (1) Plane mirrors; (2) curved mirrors. B.—Phenomena of refraction: (1) Prisms; (2) total reflection; (3) opacity caused by multiple refraction and reflection; (4) determination of the indices of refraction. C.—Selective absorption: (1) Electrically-coloured media. D.—Phenomena of interference. E.—Double refraction and polarisation: (1) Polarising gratings; (2) polarising crystals; (3) double refraction produced by crystals; (4) double refraction produced by other substances; (5) double refraction produced by strain; (6) circular polarisation; (7) magnetic rotation; (8) electro-polariscope and polarimeter. In the list of experiments above mentioned, the determination of wave-length by curved gratings has been carried out with a larger apparatus (see the current number of the *Proceedings*, Royal Society). Experiments with circular polarisation and magnetic rotation are still in progress. All the others have been repeated with the apparatus to be described below. The complete apparatus consists of—(1) a radiating apparatus emitting electric waves of short length; (2) a receiver used as a detector of electric radiation; and (3) various accessories for the study of the different phenomena.

Radiating Apparatus.

Electric oscillation is produced by sparking between two beads of platinum and an interposed sphere of the same metal. The discharge ceases to be oscillatory when the ball is roughened, and a platinum ball resists, to a great extent, the disintegrating action of the sparks. Two jointed electrodes carry the two beads at their ends. The distance between the beads and the interposed sphere can thus be adjusted. This is a matter of importance, as the receiver does not properly respond if the spark length is too large. It is more convenient to use short electric waves, and this is obtained by making the radiating spheres very small. The shortest wave-length produced is about 6mm., and the corresponding number of oscillations is about 50,000 millions in a second. The frequency of vibration in this case will be seen to be about 13 octaves lower than that which produces visible radiation. The intensity of radiation in the above case is rather feeble, and I use in general electric waves of about ½in. in length. The jointed electrodes carrying the beads are in connection with a small modified Ruhmkorff coil, actuated by a small storage cell. The usual vibrating interrupter is a source of trouble; the contact points get worn out, and the break becomes irregular. I have, therefore, discarded it in favour of a simple interrupting key. The great objection to the continuous production of

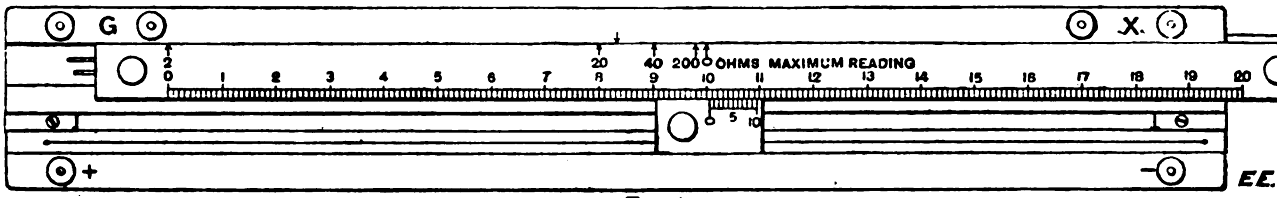

Fig. 4.

* Paper read before the British Association at Liverpool.

Digitized by Google

secondary sparks is the roughening of the surface of the radiating ball, by which the spark ceases to be oscillatory. It is very troublesome to be obliged to take out the radiator, in the middle of an experiment, for polishing. The flash of radiation produced by a single break is enough for an experiment, and it is a mere waste to have a series of useless oscillations. To economise space, I wind the condenser (a long strip of paraffined paper with tinfoil on opposite sides) round the secondary of the coil, appropriate connections being made with the interrupting key. The coil and a small storage cell are enclosed in a tinned iron box. Iron is used to screen the space outside from magnetic disturbance due to the making or breaking of primary circuit of the coil. A sudden magnetic variation disturbs the receiver. The iron box is placed inside a second box of thick brass or copper. These precautions are taken to prevent straying of electric radiation. Through a small opening behind the box the stud of the press key projects. In front of the box is the radiator tube, which may be square or cylindrical. Inside this tube is mounted the radiating vibrator. A flash of electric radiation is produced by proper manipulation of the interrupting key. The radiating apparatus may thus be made very small and portable, and requires very little attention. After the storage cell is once charged, experiments may be carried on for days, a flash of radiation being produced at any time by merely manipulating the key.

SPIRAL SPRING RECEIVER.

The receiving circuit consists of a spiral spring coherer, in series with a voltaic cell and a dead-beat galvanometer. The receiver is made by cutting a narrow groove in a rectangular piece of ebonite, and filling the groove with bits of coiled steel springs arranged side by side in a single layer. The spirals are prevented from falling by a glass slide in front. The spirals are placed between two pieces of brass, of which the upper one is sliding and the lower one fixed. These two pieces are in connection with two projecting metallic rods which serve as electrodes. An electric current enters along the breadth of the top spiral and leaves by the lowest spiral, having to traverse the intermediate spirals along the numerous points of contact. The resistance of the receiving circuit is thus almost entirely concentrated at the sensitive contact surface, there being little useless short-circuiting by the mass of the conducting layer. When electric radiation is absorbed by the sensitive surface, there is a sudden diminution of the resistance, and the galvanometer spot is violently deflected. By means of a very fine screw the upper sliding piece can be gently pushed in or out. In this way the spirals may be very gradually compressed, and the resistance of the receiver diminished. The galvanometer spot can thus be easily brought to any convenient position of the scale. When electric radiation falls on the sensitive surface the spot is deflected. By a slight unscrewing the resistance is increased, and the spot made to return to its old position. The receiver is thus re-sensitised for the next experiment. The sensitiveness of the receiver may be increased by a proper adjustment of the E.M.F. acting on the receiving circuit. The receiver at each particular adjustment responds best to a definite range of vibration lying within about an octave. The same receiver could,

Digitized by Google

however, be made to respond to a different range by an appropriate change of the E.M.F. ; very careful adjustment of this is necessary to make the receiver respond at its best to a particular range of electric vibration. For simple experiments the adjustment of the receiver is not difficult, but for delicate experiments careful manipulation is necessary. The proper adjustment of the E.M.F. is effected by taking a derived current from a circular potentiometer slide, fixed at the base of the galvanometer. A simpler way is to take a U tube, the two limbs being respectively filled with copper sulphate solution and dilute sulphuric acid. Mixture of the two solutions is prevented by an interposed plug of asbestos. A rod of copper and a rod of zinc are plunged in the two electrolytes, the whole forming a modified Daniell cell. The cell is shunted by a suitable resistance, the receiving circuit being connected to the ends of the shunt. The current flowing through the shunt, and therefore the derived E.M.F. from its ends, is varied by plunging the rods more or less in the solutions. The leading wires from the ends of the receiver are enclosed in layers of tinfoil ; the galvanometer and cell have a metallic cover with a slit for the passage of reflected spot of light. The receiving circuit is thus shielded from the disturbing action due to stray radiations. The receiver is provided with a collecting funnel. This prevents lateral waves from acting on the receiver. The funnel has two hinged side-doors by which its area—and, therefore, the amount of radiation collected—may be varied. When angular deviation is to be measured, the doors are made parallel and perpendicular to the layer of spirals. The aperture is reduced, and the receiver then only responds when the funnel points to the direction of the deviated ray. In polarisation experiments it is necessary to adjust the receiver carrying the analyser in a crossed position. This is done by a tangent screw, the rotation of the analyser being measured by means of an index and a graduated vertical disc.

Arrangement of the Apparatus.

The radiating apparatus and the receiver are mounted on stands sliding in an optical bench. Experiments are carried out with divergent or parallel beam of electric radiation. To obtain a parallel beam a cylindrical lens of sulphur or ebonite is mounted in a square tube. This lens tube fits on the radiator tube, and is stoped by a guide when the oscillatory spark is at the principal focal line of the lens. The radiator tube is further provided with a series of diaphragms by which the amount of radiation may be varied. For experiments requiring angular measurement, a spectrometer circle is mounted on one of the sliding stands. The spectrometer carries a circular platform on which the various reflectors, refractors, etc., are placed. The platform carries an index, and can rotate independently of the circle on which it is mounted. The receiver is carried on a radial arm (provided with an index) and points to the centre of the circle. An observing telescope may also be used with an objective made of ebonite with a linear receiver at the focal plane. But an ordinary receiver provided with a funnel is all that is necessary for ordinary experiments.

Laws of Reflection.

Plane Mirrors.—A parallel beam is used. The spectrometer circle is adjusted with the zero division opposite to the radiator. The platform index is turned to zero, and a plane reflector placed on a previously marked diameter at right angles to the index. The receiver is placed, say, at 60deg. The platform carrying the mirror is slowly rotated (electric radiation being at the same time produced by tapping the key) till the receiver suddenly responds. It would now be found that the platform index points to 30deg., midway between the radiator and the receiver.

Curved Mirror.—A cylindrical metallic mirror, with a radius of 25cm., is placed on the platform, with its principal axis coinciding with the platform index. When the radiator is placed at a distance of 25cm. from the mirror the source of radiation would be at the centre of the cylinder. The reflected image will now be formed at an equal distance. The receiver mounted on the radial arm (at a distance of 25cm. from the centre) is placed at a given angle; the platform is rotated till the receiver responds. The index would now be found to bisect the angle included between the radiator and the receiver.

Refraction.

Deviation of the Electric Ray by a Prism.—An isosceles right-angled prism is made of sulphur or ebonite. Parallel beam is used. For showing deviation by refraction one of the acute angles is interposed on the path of the beam.

Total Reflection.—An interesting experiment on total reflection is shown in the following way : The receiver is placed opposite to the radiator, and the prism interposed with one of its equal faces at right angles to the direction of the ray. The receiver will remain unaffected. The critical angle of ebonite being considerably less than 45deg., the rays undergo total reflection. On turning through 90deg. the receiver responds to the totally eflected ray.

Opacity due to Multiple Refraction and Reflection.—An experiment analogous to the opacity of powdered glass to light is shown by filling a long trough with irregular-shaped pieces of pitch and interposing it between the radiator and the receiver. The electric ray is unable to pass through the heterogeneous media owing to the multiplicity of refractions and irregular reflections, and the receiver remains unaffected ; but on restoring partial homogeneity by pouring in kerosine, which has about the same refractive power as that of pitch, the radiation is easily transmitted.

Determination of the Indices of Refraction.—Two semi-cylinders of the given substance separated by an air film is placed on the platform. When the radiator is placed at the principal focus of one of the semi-cylinders the rays emerge parallel into the air film, and are then focussed on the receiver by the second semi-cylinder. A metallic plate with a narrow rectangular opening is interposed between the semi-cylinders to serve as a diaphragm, and cut off all but the central rays. As the platform is rotated the incident angle on the plane surface separating the two media is gradually increased till the rays undergo total reflection When this is the case the receiver ceases to respond. The index reading is now taken, and the cylinders rotated in an opposite direction till total reflection takes place a second time. The difference of readings as given by the index in the two positions is evidently equal to twice the critical angle. Hence the value of the index can easily be deduced. A preliminary experiment gives the approximate value of the index, from which the focal distance of the semi-cylinder is roughly calculated. The spark gap of the radiator is placed at this focus, and the experiment repeated. In this way I have determined the indices of refraction of several solids for the electric ray (*vide Proceedings* of the Royal Society, vol. lix). The index of refraction of commercial sulphur is = 1·73; that of a specimen of pitch = 1·48

Indices for Liquids.—A cylindrical trough is filled up with the given liquid ; two thin parallel glass plates enclosing an air film are vertically placed so as to divide the liquid cylinder into two halves. The readings for total reflection are taken as in the last case. The index for coal tar I found to be 1·32.

Selective Absorption.

A substance is said to be coloured when it allows light of one kind to pass through but absorbs light of a different kind If we take into account the entire range of radiation there is hardly a substance which is not in this sense coloured. In the spectrum of radiation transmitted through glass for example, two broad absorption bands would be observed, one in the ultra-violet and the other in the infra-red, the electric and the visible rays being not absorbed to any great extent. A brick or block of pitch would absorb light, but would transmit the electric ray. On the other hand, a stratum of water, though transparent to light, would absorb the electric ray. These substances exhibit selective absorption, and are therefore coloured. If we only take into account the electric radiation it would no doubt be found that radiations having different wave-lengths are unequally absorbed by different substances.

Phenomena of Interference.

Determination of the Wave-Lengths by Diffraction Grating.—In a paper read before the Royal Society in June last I have given an account of a method of obtaining pure spectra of electric radiation by means of a curved grating. The experiment was carried out with a large apparatus. The spectrum obtained was well defined, and appeared to be linear, and not continuous. I had not time to adapt the experiment to this small apparatus, but I think it would not be difficult to do so.

Double Refraction and Polarisation.

The spectrometer circle is removed, and an ordinary stand for mounting the receiver substituted. By fitting the lens tube, the electric beam is made parallel. At the end of the lens tube there is a slot, in which is dropped the wire grating polariser. A crystal-holder provided with three sliding jaws is fitted on to the lens tube, and is capable of rotation round an axis parallel to the direction of the electric ray. The receiver carrying the analyser is also capable of rotation round a horizontal axis by means of a tangent screw. The angular rotation is measured by means of an index fixed to the analyser and a graduated vertical disc. The gratings are made by winding fine copper wire parallel round square frames. Other forms of polariser will be described later on. The spark gap is placed vertical, and the polariser is adjusted with wires horizontal. The emergent beam is now completely polarised, the vibration taking place in a vertical plane passing through the axis. The analyser fitted on to the receiver may be placed in two positions: (1) parallel position—when both the gratings are horizontal ; (2) crossed position—when the polarising grating is horizontal and the analysing grating vertical. In the first position, the radiation being transmitted through both the gratings, falls on the sensitive surface, and the galvanometer responds. The field is then said to be bright. In the second position the radiation is extinguished by the crossed gratings, the galvanometer remains unaffected, and the field is said to be dark. But on interposing certain crystals with their principal planes inclined at 45deg. to the horizon the field is partially restored, and the galvanometer spot sweeps across the scale. This is the so-called depolarisation action of double-refracting substances.*

Experiments with Wire Gratings.—A wire grating at 45deg. interposed between the crossed analyser and polariser partially restores the field, but ordinary wire gauze does not transmit any radiation, the action of one set of wires being neutralised by that of the other set at right angles.

Double Refraction Produced by Crystals.—The crystals to be examined are mounted on the holder, and properly inclined. Double refraction is shown by all crystals belonging to the rhombic, rhombohedral, triclinic, and monoclinic systems. The effects exhibited by the following are very marked : (1) Serpentine : This crystal, which appears fibrous, transmits the ordinary and the extraordinary rays with unequal intensity. A fairly thick piece would absorb vibrations

* For a detailed account of experiments on the polarisation of the electric ray, I would refer to my paper read before the Asiatic Society of Bengal, May, 1895.

Digitized by Google

parallel to the fibres, and transmit vibrations perpendicular to the fibres. Ordinary radiation, after transmission through a thick piece of serpentine, would be plane polarised, the vibration taking place perpendicular to the fibres. (2) Nemalite: This crystal exhibits this effect in a still more marked degree. (3) Tourmaline also produces the depolarisation effect. The difference in absorption of the ordinary and the extraordinary rays is, however, not so great as in the case of light. (4) Beryl is also very good crystal for exhibiting the depolarisation effect.

Polarisation Produced by other Substances.—I found many other natural substances producing polarisation, the most interesting being vegetable fibres. Common jute (*Corchorus capsularis*) exhibits the property in a very marked degree. I cut fibres of this material about 3cm. in length, and built with it a cell with all the fibres parallel. I subjected this cell to a strong pressure under a press. I thus obtained a compact cell 3cm. by 3cm. in area and about 5c.m. in thickness. This was mounted in a metallic case, with two openings about 2cm. by 2cm. on opposite sides for the passage of the radiation. This cell was found to quench vibrations parallel to the fibres, and transmit vibrations perpendicular to the fibres. Jute cells could thus be made to serve as polarisers or analysers.

Effect Due to Strain.- Could be exhibited by stratified rocks, the plane of stratification being inclined at 45deg. to the horizon.

Effects similar to that produced by unannealed glass can be imitated by a block of unequally chilled paraffin.

The polarisation apparatus above described may also be used as a polarimeter, the rotation of the analyser being measured by the graduated disc.

COMPANIES' MEETINGS AND REPORTS.

WILLANS AND ROBINSON, LIMITED.

The fifth half-yearly report of the directors of this Company for the period ended June 26, to be submitted at the general meeting to be held at the Cannon-street Hotel on October 7, states that, after writing off depreciation from plant, patents, etc., the sum of £4,040, and paying a small amount of interest accrued upon the recently-issued debenture stock, the balance to the credit of profit and loss account for the half-year (including £821 brought forward) is £12,877. Out of this the directors propose that dividends be paid at the full rate of 6 per cent. per annum on the preference shares, and at 7 per cent. per annum, as before, upon the ordinary shares, together taking £7,312. The amount payable to the directors, in accordance with the articles of association, is £1,423, and it is proposed to carry £2,500 to the reserve fund, raising the amount to £10,146 as the result of 2½ years' working. The balance, £1,641, it is proposed to carry forward. The debenture stock authorised to be created by the resolution passed at the last general meeting was issued in May, at par, the rate of interest being 4½ per cent. per annum, and was largely over-subscribed. The directors were advised to fix the issue at £100,000, rather than at the smaller amount they had in view at the date of the last meeting. The growth of the business in the present year leaves no doubt that the larger amount can be utilised with advantage. The expenses connected with the above issue amounted to £1,151, which sum appears on the present occasion as a credit in the balance-sheet. As the debenture stock is repayable after a term of years, it would be proper to write off the expenses by a small half-yearly charge extending over the same term; but it will probably be felt that so small a sum ought to be dealt with immediately, as, for instance, by writing it off at once out of the balance to be carried forward in the profit and loss account. To this it may be objected that the balance in question is surplus profit, and therefore has already contributed to the contingent salaries of the directors and staff, whereas, strictly, the cost of the debenture issue is in the nature of an expense, which should reduce the surplus profits, and therefore the contingent salaries. If, on the other hand, the amount is written off at once, and the contingent salaries are reduced in proportion, it will fall somewhat hardly upon the present holders of office, who will bear a charge which ought partly to fall upon their successors. It is not urgent that the question be settled upon the present occasion, and, as the directors' own interests are involved, they trust to receive some expression of opinion on the part of the shareholders, as a basis for action to be taken next half-year. The Company's shares were granted a quotation by the committee of the Stock Exchange last May, and a quotation of the debenture stock (provisional certificates) has since been given. The works of the Company continue to be very fully employed; in fact, orders are in hand for a long period in advance. Work will shortly be commenced in the new shops at Rugby. The report is signed by the chairman, Mr. Mark Robinson.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

Directors: J. B. Braithwaite, jun., Esq. (of Messrs. Foster and Braithwaite), chairman; Arthur Ayres, Esq., M.I.C.E; Aymor H. Sanderson, Esq.; Colonel Frederick George Steuart; B. H. Van Tromp, Esq.; Edward Woods, Esq. (past-president Institution of Civil Engineers). Joint managers: John S. Raworth, M.I.C.E.; R. Percy Sellon, M.I.E.E.

The seventh annual report of the directors, to be presented to the shareholders at the general meeting of the Company to be held at Cannon-street Hotel, London, E.C., on Monday, October 5, at 12 o'clock noon, states that the profit and loss account shows a gross profit of £33,736. After deducting general charges, maintenance of buildings, plant, and patents, staff bonuses under the Company's profit-sharing scheme, bank interest, and interest on first and second debenture stock, there remains a net balance of profit for the year of £4,615. The directors regret that the profits for the year are not larger. The result is attributable partly to a general falling off in the volume of central-station electricity supply contracts and partly to the prevalence of unduly low prices for electrical machinery. The directors anticipate, however, that the future demand for electric traction plant will fully compensate for the shrinkage of orders for electric lighting machinery, while with regard to prices they are glad to state that there are some indications of improvement. Meanwhile, every effort has been made to minimise general and administrative charges, there having been the substantial reduction of nearly £4,000 which has been effected during the year. The directors anticipate still further reductions during the current year. During the past year the directors have accepted an offer from one of the large Continental manufacturing firms for the purchase of the Vienna factory. The amount realised fully reimburses the Company for its capital outlay on the business, and the sum resulting from the transaction, which was upon a cash basis, appears under the items relating to cash in the balance-sheet. In deference to the wish expressed by shareholders at recent annual general meetings, and, in view of the disposal during the year of the Company's Vienna factory, the directors consider the present a convenient opportunity for sub-dividing the capital item of property, patents, and goodwill, which has hitherto appeared as a single item in the balance-sheets. With this object they have obtained a full report from Messrs Fuller, Horsey, Sons, and Cassell, whose valuation of the Company's freehold works, together with the fixed plant, machinery, loose tools, and utensils, at Loughborough, Leicestershire, amounts to £83,847, and of the leasehold factories at Lambeth and Southwark, to £5,000, together value £88,847. Deducting this sum from the amount of £295,244, representing the agregate value of the undivided items of property, patents, and goodwill, it will be seen that a balance of £206,397 is represented by patents and goodwill. While many valuable patents owned by the Company are still included in the item of patents, the early patents in connection with electric lighting, for which large sums were originally paid by the Company, have now mostly expired. In order to deal effectively with the position thus arising, the directors strongly recommend the shareholders to write off £1 per share from the nominal value of the ordinary shares of the Company. This will produce a figure of £90,000, which it is proposed to apply during the current year to reduction of the item of patents and goodwill, and to eliminating from the books such of the items included in the suspense account appearing in the balance-sheet as may prove to be valueless. The directors have placed to this suspense account all assets standing in the books of the Company which they consider to be in any way doubtful; and the step now recommended, upon receiving the sanction of the shareholders, will ensure that profits of future years shall not be hampered by the uncertainty attaching to the doubtful assets referred to. A resolution to carry out this recommendation will be submitted to an extraordinary general meeting to be held at the close of the ordinary meeting. Subject to this recommendation being adopted by the shareholders, the directors propose to pay to the preference shareholders the balance of dividend due to them from last year, amounting to £2,141, and to carry forward the balance of £1,654 which remains after clearing off the debit of £820 brought forward from last year. In accordance with the shareholders' approval at the last annual general meeting of the decision to create an issue of £105,000 4½ per cent. redeemable second debenture stock, £76,770 of such stock was allotted in the autumn of last year. During the year under review the Company have sub-leased the Lambeth factory for the remainder of their term; and have transferred the final remnant of their London manufacturing operations to Loughborough, where the whole of the Company's manufacturing is now concentrated. An important contract has been secured from the British Electric Traction Company for the equipment of the North Staffordshire tramways system with electric traction. There is every indication that electric traction will be largely adopted in this country in the immediate future; and the position of the Company in regard to the undertaking of works of this character is exceptionally favourable, having regard to their command of ample working capital, and to the fact of their being manufacturers of rolling-stock and tramway material as well as of electrical plant. The contracts with the County of London and Brush Provincial Electrical Lighting Company for the equipment of electricity supply stations in St. Luke's, Middlesex, and the Wandsworth district have been in progress during the year, and it is expected that a supply of current will be available in both areas during the coming winter. The contract with the Government of Malta for the establishment of an electricity supply station for the lighting of Valetta and of the Government establishments is now practically completed, and the result has given general satisfaction. During the year the "Universal" steam-engine, to which the attention of shareholders was drawn last year, has been developed, tested, and placed upon the market. Orders are in course of execution for central electricity supply stations, factories, mining works, etc. The Company are introducing a type of alternating-current dynamo, new to this country, for which they hold important patent rights. This dynamo possesses valuable features which the directors believe are likely to command for it a ready sale. The following is the balance-sheet of the Company:

Digitized by Google

BALANCE-SHEET, JUNE 30, 1896.

Dr.	£	s.	d.	£	s.	d.
Authorised capital	750,000	0	0			
Capital issued—viz., 90,000 6 per cent preference shares of £2 each, £180,000; and 90,000 ordinary shares of £3 each, £270,000				450,000	0	0
4½ per cent. perpetual first debenture stock				125,000	0	0
4½ per cent redeemable second debenture stock ...				76,770	0	0
Creditors—Sundry creditors, £28,982. 16s. 2d.; bills payable, £4,602. 18s.				33,585	14	2
Loan from bankers				26,775	0	0
Balance of profit and loss account, subject to realising the whole of the suspense account, *per contra*	4,615	9	8			
Less balance as per last account	820	7	4			
				3,795	2	4
				£715,925	16	6

Note.—Contingent liability in respect of uncalled capital on shares in other companies, £11,142. 10s.

Cr.	£	s.	d.	£	s.	d.
Property — factories at Loughborough, Lambeth, and Southwark	88,847	0	0			
Patents and goodwill	206,397	8	9			
				295,244	8	9
Stock	124,031	8	2

Less amounts transferred to suspense account	7,912	10	0			
				56,454	6	7
Suspense account, consisting of amounts transferred from stock, debtors, and shares and debentures in other companies :						
Transferred from stock	23,368	11	9			
Transferred from debtors	24,158	6	2			
Transferred from shares and debentures in other companies	7,912	10	0			
				55,439	7	11
				£715,925	16	6

The auditors, Messrs. Cooper Bros. and Co., append the following note:

"We have examined the above balance-sheet with the books, accounts, and vouchers of the Company, and in our opinion, subject to the following remarks, it is properly drawn up so as to exhibit a correct view of the Company's affairs on June 30, 1896. We have verified the cash balances and the shares and debentures in other companies. The latter are considered by the Board to be of the full value stated in the accounts, but as to a part of them we are not able to verify the market value. It will be noticed from the directors' report that the assets transferred to the suspense account are considered doubtful, and we have not means of ascertaining their value. We have also verified the securities held by the trustees of the employés bonus scheme."

APPROPRIATION ACCOUNT.

(Subject to adoption by the shareholders of the recommendation of the directors to reduce the nominal value of the ordinary shares by £1 per share.)

Dr.	£	s.	d.
Balance of dividend due to preference shareholders for year ended June 30, 1895	2,141	3	8
Balance carried forward	1,653	18	8
	£3,795	2	4
Cr.	£	s.	d.
Balance	3,795	2	4
	£3,795	2	4

A summary of the profit and loss account is given at the beginning of the directors' report. On the credit side the only items besides gross profits are dividends on securities £330 odd, and transfer fees £107. On the debtor side maintenance of buildings and plant cost £3,048.

The Blackwall Tunnel.—The passage from end to end has now been opened through, and a small party of about 12 went through it for the first time on Wednesday. The electric lighting plant has been ordered.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Dresden.—Tenders for 3,710 wooden telegraph posts for the Saxon State Railways are receivable at Dresden on October 15.

Bucharest.—Tenders will be received at the Mairie, Bucharest, on November 16 for two stand-by steam-engines for a water-power electric generating station at Grozavesti.

Aarhus (Denmark).—Tenders will be received on October 8 by the State Railway Administration at Aarhus (Telegraphen sections Contoir) for the supply of a large quantity of sulphate of copper.

Leyton.—Tenders will be received by the Urban District Council on October 6th for installing the electric light in the public library. Particulars are obtainable at the surveyor's office, Town Hall, Leyton.

Madrid.—Tenders will be received on October 12 by the Direccion General de Correos y Telegrafos at Madrid for the supply to the Spanish Government of 60,000 telegraph insulators. The upset price is 1 peseta (9½d.), and a 10 per cent. security will be required.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Paris.—The French Telegraphic Authorities have offered for tender the supply and laying of a four-wire submarine telephone cable between France and England. The date for sending in tenders is October 20, but application for permission to tender must be made before October 5 to the Under Secretariate of Posts and Telegraphs, Paris, rue de Grenelle 103.

Brussels.—Tenders will be received on October 21 for the supply to the Belgian telegraphic service of (1) a quantity of galvanised iron wire, (2) various lengths of cable for riverine, submarine, and land service, and (3) a quantity of bare and insulated copper wire. No details are advertised as to the amounts required, but particulars are obtainable at the Brussels Bourse.

Werl (Germany).—The Local Authorities propose to submit to tender the construction and maintenance of an electric power and lighting generating station, and also an electric tramway from Werl to Wikede, with an eventual extension to Hamm. Further particulars will be obtainable at the Rathhaus, Werl-i.-Westf., Germany. The date for the tenders is November 3.

Paris.—Tenders will be received on October 13, at the Under Secretariate of Posts and Telegraphs, Paris, rue de Grenelle 103, for the supply of about 70 tons of 2½ millimetre galvanised iron wire (special), 50 tons ordinary galvanised wire (5mm.), and 100 tons of 7mm. wire; also a quantity of jute wrapping. Application for permission to tender must be made by October 6.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Mayaguez (Puerto Rico).—The Secretary of State for Foreign Affairs has been informed by H.M. Ambassador at Madrid that the Spanish Government have invited tenders for the construction and working of a telephone system in Mayagüez, Puerto Rico. The date fixed for the consideration of tenders is October 8, and such particulars as have been received may be inspected at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

Brussels.—Tenders will be received on October 21, at the Bourse, Brussels, for installing the electric light at the Arlon Railway Station, including the offices and works. Particulars are obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Leeds.—The Council require tenders for the supply and erection of No. 2 overhead travelling cranes for the engine-house of the tramways electricity generating station, The Calls, Leeds. Tenders, endorsed "Tender No. 8 for Cranes," must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than 12 noon on October 13. Particulars, plans, and forms of tender may be had from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

Madrid.—The Secretary of State for Foreign Affairs has received a despatch from H.M. Chargé d'Affaires at Madrid stating that a free public competition is announced in the *Gaceta de Madrid* of September 4 for the grant of the contract for the construction and

Digitized by Google

establishment of three submarine cables to join the islands of Luzon, Panay, Negros y Cebu, in the Philippine Archipelago. Tenders must be lodged within 90 days of the publication of the conditions at the Spanish Ministry of the Colonies, accompanied by a deposit of 50,000 pesetas. The particulars received can be seen at the Commercial Department of the Foreign Office between the hours of 11 and 6.

Dundee.—Tenders are invited for boiler, fittings, steam pump and piping, wiring, fittings, accumulator batteries, steam and oil engines and dynamos, for the electric lighting of the Dundee Royal Lunatic Asylum. Sealed tenders to be sent to the secretary, Mr. Robert C. Walker, 5, Whitehall-street, Dundee, endorsed outside "Electric Lighting Tenders," by noon on October 9. Specifications and forms of tender may be obtained from the Engineer on deposit of £1. 1s., which will be returned on receipt of bona fide tenders. Plans, etc., may be seen on application to Mr. Walter H. Tittensor, electrical engineer, Dudhope, Crescent-road, Dundee. No copies will be supplied.

Christiania.—The Secretary of State for Foreign Affairs has received a despatch from her Majesty's Consul-General at Christiania stating that tenders are invited for the delivery of 22,000 linear metres (13 miles 1,180 yards) of rails, with the accompanying fishplates and screws, for the electric tramline to be constructed between Christiania and Holmenkollen. Tenders are to be sent in sealed envelopes, marked "Aubud," by October 15, 1896, to the Tramline's Offices, 47, Kirkeveien, Christiania, where the conditions can be procured. The rails must be delivered in Christiania by January 1, 1897. Further particulars on the subject are expected from her Majesty's Consul-General, and will be on view as soon as they have arrived at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 6 p.m.

Morley.—The Electric Lighting Committee of the borough of Morley are prepared to receive tenders for the supply and erection of the following plant. (The whole bound up in one specification; price £2. 2s., returnable on receipt of a bona fide tender): Section A—Boiler-house plant: Lancashire boilers and fittings, feed pump, etc. Section B—Engine-house plant: steam alternators and exciters, motor alternator, accumulators, steam and exhaust pipes, valves, etc. Section C—switchboard and instruments. Section D—overhead crane. Section E—underground work: cables and stoneware culverts. Section F—transformers and switchboards. Section G—arc lamps, posts, and accessories. Section H—meters. Tenderers are at liberty to tender for any section, but not for part of a section. The ground plans of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E.C., on payment of £2. 2s. for each copy, which sum will be refunded on the return of the specification, filled up with a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to the town clerk, Mr. R. Borrough Hopkins, at the Town Hall, Morley (Yorks), and be delivered on or before Wednesday, October 14.

BUSINESS NOTES.

Metropolitan Electric Supply Company, Limited. —The directors have declared an interim dividend of 4s. per share for the half-year.

Bridlington Quay.—Messrs Whittaker Bros., of Horsforth, propose to build a large hotel, which is to be fitted throughout with electric light

Liverpool.—The Lighting Committee of the Corporation have decided to recommend a scheme for the electric lighting of London-road and Lime-street.

Hove Electric Lighting Company, Limited.—The directors have declared an interim dividend for the half-year to June 30 last at the rate of 4 per cent. per annum.

Postal Telegraph Cable Company.—The directors of the Postal Telegraph Cable Company, 253, Broadway, New York, announce a quarterly dividend of 1 per cent. on the capital stock.

Coventry.—At the meeting of the City Council the corporate seal was affixed to a mortgage of the general district fund for raising £9,000 at 3 per cent. in respect of electric lighting.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—The directors have declared an interim dividend for the quarter ended June 30 last of 2s. 6d. per share, free of income tax.

Windermere.—In respect to the agreement with Mr. Fowkes as to the lighting of the electric lamps, the Urban District Council have left it with the Highways Committee to complete the arrangements.

Removal.—Mr. Sidney à Court has removed from 19, Old Queen-street, S.W., to more commodious offices in Artillery-mansions, 75, Victoria street, S.W., to which building he is consulting engineer

Isle of Man Tramways and Electric Power Company, Limited.—The directors recommend an interim dividend for the past six months at the rate of 7½ per cent. per annum on the ordinary share capital.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending September 27 amounted to £1,168, as compared with £1,266 in the corresponding week of the previous year, being a decrease of £98.

West Ham.—The District Council have approved of the electric lighting scheme prepared by their electrical engineer, Mr. J. J. Steinitz, and it is proposed to borrow £50,000 for the purpose.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending September 25 were £2 223. 19s., compared with £2 062 2s. 8d. for the corresponding period of last year, being an increase of £161. 16s. 4d.

Chiswick.—At a meeting of the District Council the Surveyor, in reply to a question with reference to the electric lighting station, said that as things stood at present the electric lighting system could be established in four or five months.

The Czar's New Yacht.—The new Russian imperial yacht, the "Standart," in which the Russian Emperor went to Scotland, is lighted throughout by electricity. The yacht is 425ft. in extreme length, and the engines have a total of 15,000 h.p.

Heathman's Ladders—We are informed that no less than 10 of Heathman's patent telescopic tower ladders are now employed by the arc lamp trimmers of Edinburgh City, and similar ladders have been recently supplied to Fort William, Ayr, Glasgow, and Dover.

New Mutual Telephone Syndicate, Limited.—This Company has been registered as a guaranteed company, with a membership of 20, each of whom is liable for the sum of £100 in the event of winding-up, to carry on the general business of a telephone company.

Automatic Time Switches.—The Keighley Electrical Engineering Company, Limited, of Alexandra Works, Keighley, Yorks, send us catalogues of automatic time switches, registers, and time-checking machines, and electrical apparatus, and machinery.

The Jandus Arc Lamp.—Messrs. Drake and Gorham send us a list of testimonials they have received from users of the Jandus arc lamp among which we notice one from Dr. J. T. Bottomley, of the University of Glasgow, and another from Mr. W. H. Preece, C B.

Personal.—The Huxley Scholarship of £60 for three years at the Central Institution, South Kensington, has been awarded to Mr. J. M. Donaldson, who was formerly under Mr. W. Perren Maycock, of Croydon, and subsequently proceeded to Finsbury Technical College.

Croydon—The electric lighting of the Town Hall having been so successful, the Thomson-Houston Company, who are the contractors for the installation, have received permission to begin the lighting of private houses. North End is shortly to be lighted with arc lamps.

Electric Lighting Extension Syndicate, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares, to enter into an agreement with H. C. Hodges and C. O. Bastian, and to carry on in London and elsewhere the business of suppliers of electricity in all its branches.

City and South London Railway.—The returns for the week ended September 27 were £925, compared with £823 for the corresponding period of last year, being an increase of £102. The total receipts for the half-year 1896 were £11,813, compared with £10,971 last year, being an increase of £842.

Tunbridge Wells.—We are informed that the enlargement of the electric lighting station is now practically complete, and that additional machinery will be running shortly. So fast is the use of the electric light extending that a further extension of the works will soon have to be considered.

Bexhill—A letter from the parliamentary agents in reference to the steps to be taken with regard to the proposed insertion of a purchase clause in the Bill about to be promoted by the electric lighting company was read at the meeting of the Urban District Council, and referred to the Highways Committee.

Telegraphs in the States.—According to reports from the United States, the Postal Telegraph Company has taken over the telegraph lines of the Chesapeake, Ohio, and South-Western system heretofore operated by the Western Union. The system covers 400 miles of railway, 1,500 miles of wire, and 50 offices.

London.—The reopening of the Church of St. Mildred, Bread-street, which has been closed for cleaning and the installation of the electric light, will be delayed for probably six months. The concrete floor, which covers the old burial vaults, has cracked and sunk, owing, it is believed, to the weight of the scaffolding erected for the purpose of cleaning the church.

Dundee.—A Bill has been prepared by the Town Council to obtain additional borrowing powers for an extension of the electric lighting system. So far little has been done in lighting the streets by electricity, but it is now proposed to take a forward step in this direction. Various officials have been asked to report on the matter, which will be dealt with at an early meeting of the Board.

Paterson and Cooper.—The business of Messrs. Paterson and Cooper, of European Works, Pownall-road, Dalston, electric light and power and telephone engineers and contractors, is being carried on by the trustee, Mr. Edward C. Moore, pending a sale to, or amalgamation with, some business of a similar character. The showrooms are at Victoria-street, Westminster, and at Glasgow.

Forthcoming Exhibition.—We have received particulars of the Hardware, Machinery, Ironmongery, Inventions, Electrical, and Allied Trades' International Exhibition and Market, which will be held in the Royal Agricultural Hall from August 2 to 9, 1897. An exhibition on similar lines, but applying particularly to electricity, will be held at the same place from June 23 to 30, 1897.

Digitized by Google

The Central London Railway.—Mr. A. Cates, the umpire, has now issued his award in reference to the claim for compensation brought by the Duke of Bedford against the Central London Railway Company. The property taken comprised 133, 134, 135, and 136, High Holborn, the site of which is to form the British Museum station of the Central London Railway. The award is for the sum of £9,279.

Hoylake and West Kirby.—At a meeting of the General Purposes Committee, which was held just before the District Council meeting, resolutions were passed that no action should be taken in promoting a Bill for purchasing the undertaking of the gas and water company, and that the Council should make application for electric lighting powers for the district. At the Council meeting these recommendations were confirmed.

Sheffield. After their return to England on Tuesday next, the motor deputation appointed by the Sheffield City Council will visit a number of towns, including, possibly, Bristol, Edinburgh, Glasgow, Blackpool, etc., and then they will present to the Corporation a full report of their doings. It is expected that the report will run much on the same lines as that of the Glasgow deputation, which, it will be remembered, strongly recommended the adoption of the overhead system.

New and Mayne, Limited.—This Company has been registered, with a capital of £150,000, to acquire the business carried on by A. G. New and A. J. Mayne, trading in co-partnership as New and Mayne, at Palace-chambers, 10, Bridge-street, Westminster, Woking, and elsewhere, and to carry on the businesses of electrical engineers and contractors, electricians, manufacturers and suppliers of electricity for heat, light, or motive power, and appliances of all kinds used in connection therewith, etc.

Horsfall Engineering Syndicate, Limited.—This Company has just been registered, with a capital of £50,000, to carry on at Leeds and elsewhere the business of makers or builders of furnaces for the destruction of town or other refuse, or for general purposes, to construct, maintain, and work any machinery or plant for the generation of electricity, to be used for lighting or other purposes, to undertake the supply of electricity to public bodies or private consumers, and to carry on the business of mechanical engineers.

Dewsbury.—In addition to the wiring of the technical school classrooms and corridors, etc., now being proceeded with by a large staff of men in the employ of Mr. A. Richmond Turner, the contractor, an installation is being put into the warehouses and offices of Messrs. F. W. Reuss and Co. There will be an addition to the number of shops using incandescent lamps, and probably orders for others to be supplied with the electric current will shortly be handed in to the Lighting Committee of the Corporation. The prospect for the coming season is regarded as good.

Portsmouth.—During the annual meetings of the Free Church Federation of Hampshire and Portsmouth and District Nonconformist Association in the town hall, and while an organ recital was proceeding, the building, which is illuminated with the electric light, was plunged into total darkness. It was afterwards announced that Alderman G. Ellis (chairman of the Electric Lighting Committee) had sent a message to say that one of the main cables had failed and could not be repaired that night. A supplementary cable was afterwards put in, and the light was switched on about nine o'clock.

Southwark.—The Works Committee recommended, at the meeting of the St. George's Vestry, that permission be given to the National Telephone Company to lay underground mains throughout the parish at a rental of £500 per annum to the Vestry for the privilege. Mr. Hilton opposed this extravagant charge. The Telephone Company had largely assisted the commercial community; the Vestry should review their proposal. He moved that the matter be referred to the committee in order that a deputation might wait upon the company to consider terms. Mr. Redman said that, as the Telephone Company was prosperous, they should pay a commensurate rent. The amendment was adopted.

Change of Address.—Messrs. H. M. Salmony and Co., electrical engineers, of London and Birmingham, have removed their offices from 61, Charing Cross-road, London, W.C., to 118-120, Charing Cross road. The removal is in every respect a desirable one. The new premises are very capacious and roomy, and when finally fitted up will look very imposing. There is a useful basement, a convenient saleroom, showrooms, offices, and storerooms, and Messrs. Salmony have the whole of the five floors at their disposal. All the latest designs and improvements in electric machinery and fittings and telephonic apparatus will be shown to the best advantage, and handsome arc light brackets have been fixed on the front of the building.

Motor Carriages.—What is claimed to be the first catalogue of motor carriages has just been issued by Messrs. Julius Harvey and Co, 11, Queen Victoria street, London, E.C. The little book, which is very well got up, contains illustrations and particulars of motor carriages at prices ranging from £130 for two-seated carriages to £300 for six-seated carriages. Their motor omnibus or commercial traveller's carriage can be obtained for £325, and details are also given of motor delivery vans and motor cycles. The vehicles all appear to be of light construction and elegant design, if the illustrations afford any criterion. At the end of the catalogue is published a reprint of the new Act of Parliament relating to the use of motor carriages.

Hanley.—At a recent Town Council meeting the Electric Lighting Sub-Committee reported that, owing to the increased demand for electricity, it was desirable that advantage be taken of the clause in the agreement with Messrs. Ferranti for the provision of a second engine, and that further application to the Local Government Board for borrowing powers be made. They recommended that the second engine for the electricity works contracted to be supplied by Messrs. Ferranti for the sum of £3,300 be ordered. In moving the adoption of the report, the Chairman said the electric installation was paying its way, and that with a reduced charge per unit it was calculated that the Council would not lose anything. The motion was agreed to.

Derry.—At the meeting of the Lighting Committee of the Corporation a report was read from the Lamp Committee embodying the recommendations and suggestions as to changes, etc., in position of electric light columns made by the members who drove round to inspect. The committee read a number of recommendations, including removals repairs, and relighting, and after a brief discussion the recommendations were ordered to be carried out. It was ordered to advertise for tenders for coal for the generating station. Mr. Christie, electrical engineer, read a report respecting the additional cost of keeping all the electric lamps lighted from dusk till daylight. The cost of running the light for 12 months was £2,026, and he estimated that to keep all the lamps alight from dusk till daylight would cost about £400 a year more.

Leicester.—At a quarterly meeting of the Town Council, Alderman Lennard submitted the financial statement of the Gas and Electric Lighting Committee for the past half-year, showing that the net profit, after paying interest on the capital of the undertaking, was £11,571. 0s. 10d., out of which £3 262 had been paid to sinking fund, leaving a balance of £8,309 to be applied at the end of the financial year as the Council might direct. The result of the working of the electric light department for the half year was a loss, after charging £584 on sinking fund account, of £723. 0s. 5d., after taking credit for £151, the profit from the electric lighting fitting business. The total loss in connection with this department now amounted to £2,060, but Alderman Lennard was very sanguine that the next half-year's working would wipe off the loss during the past six months, and that in 12 months' time the department would pay a profit that would recoup the loss on the first year's working. The report was approved.

Birmingham.—A proposal is on foot to connect Walsall and Birmingham by a tramway. Messrs. A. Dickenson and Co., electrical and civil engineers, Birmingham, acting on behalf of clients, recently made application to Walsall Town Council and to Staffordshire County Council asking permission for the line to be laid, and these bodies have asked for particulars, which are now in course of preparation. Walsall Town Council, who perhaps have the largest interest in the route, are generally favourable to the proposal, subject, of course, to an agreement being come to on points of detail. The idea of the promoters of the scheme for whom Messrs. Dickenson and Co. are acting is to take advantage of the powers conferred by the Light Railways Bill and construct an overhead electric traction along that part of the country road between Perry Barr and Walsall, though in the more thickly-populated district the line would be laid as an ordinary tramway. It will be a line somewhat similar to that between Kidderminster and Stourport.

Hawaii.—The report of the directors of the Hawaiian Tramways Company, Limited, for the year ending June 30 last, to be presented to the general meeting to be held at the Cannon-street Hotel on October 6, states that a change of the motive power to electricity has been under the serious consideration of the directors. A report has been furnished by an agent of the General Electric Company, of Boston, U.S.A., who visited Honolulu specially for that purpose, and estimates based on his report have been made. These estimates have been carefully gone into, and in view of the cost of a conversion the directors cannot feel justified in recommending the introduction of electricity under the existing concession held by this company. The authorities have, however, been approached, and it is hoped that certain facilities may be granted which will remove the present difficulties and enable the company to carry out an alteration which would undoubtedly be popular in Honolulu, and, under conditions, might be of advantage to the shareholders.

Non-Magnetisable Watches.—We have received from Messrs. Smith and Son, of 9, Strand, W.C., their catalogue of watches and clocks. With regard to the former you take your pick between gold, silver, steel, nickel, and aluminium. Messrs. Smith and Son, however, lay special stress upon the attention they pay to non-magnetisable watches. There is no particular reason—except old custom and the inherent conservatism of human nature—why all watches should not be made non-magnetisable now that a magnetic field is as much a thing to be reckoned with as a change of temperature. But some watches are not new and others are still made with a steel balance in the old way, consequently Messrs. Smith and Son announce that if they are lever watches they can be made practically non-magnetisable for from £2 to £3. If the customer wants such luxuries as palladium hair springs he must naturally pay more. With a Swiss watch it appears that the best thing to do is to change it for another, as the expense comes to much the same.

Brighton.—The application of the National Telephone Company for permission to lay wires underground in various streets has been again before the Works Committee of the Town Council. The borough surveyor furnished a report on the subject, in which he stated that the company had amended the route according to his suggestion; but he reminded the committee that several lines of wires would be laid, and that manholes would have to be constructed at intervals of 150 yards, and also at all points where a deviation in the line became necessary. As the streets are narrow

Digitized by Google

and there is a probability that either they may frequently be broken up to obtain access to the wires, or the manholes will be frequently in use, the matter resolved itself into one of principle and expediency. The surveyor therefore urged upon the committee that they should consider whether the underground or the overhead system is best in the interests of the public. The committee decided to grant the permission asked for. Preparations are being made for extending the electric lighting of Brighton along the Lewes road, the work of excavating the road for the reception of the lofty lamp-pillars having been started.

Fulham. -The Vestry have received a letter from the County of London and Brush Provincial Company, Moorgate-street, stating that they should be glad before a final decision was arrived at by the Vestry with respect to applications for provisional orders to have the opportunity of attending and placing fully and fairly before them the advantages which they considered they should be able to offer them with respect either to taking over the order which they might obtain, or as to the terms which they would agree with them beforehand, as was done last year in the case of their application from Camberwell. They might mention that their station at Wandsworth was now approaching completion. The delivery of plant had been commenced, and they would be in a position to supply current from there and for the coming winter's lighting. Their mains were already laid to Putney Bridge, and in the event of the Vestry consenting to their proceeding with their application they could continue along across Putney Bridge, laying their mains throughout their district and giving a supply direct by the autumn of 1897. They would also propose to make it part of their agreement that the Vestry should have the option of purchase within a short term of years of the whole of the distributing mains. The letter has been referred to the Electric Lighting Committee.

Maidstone.—At the meeting of the Urban District Council the Electric Lighting Committee reported that they had received formal notice that the Municipal Electric Light and Power Corporation, Limited, intend to make application to the Board of Trade for a provisional order under the Electric Lighting Acts; that they had received from Mr. W. C. C. Hawtayne a new proposal for carrying out the Council's provisional order, and the committee were making full enquiries in reference to the same; that they had received a letter from Mr. Thomas King to the effect that he proposed to place electric lighting cables across certain streets in the borough unless the Council intended to proceed at once with the powers under their provisional order. The committee had replied that they were fully considering the whole question, and could not recommend the Council to grant him permission to place any wires across the street. Alderman Ellis, in moving the adoption of the report, said he thought the subject of electric lighting was dead for 12 months, according to the decision of the Council; but the town clerk had received the communications mentioned in the report, which of course reopened the matter again to a certain extent. The report was adopted. The apparatus for making use of the Röntgen rays in connection with surgery is about to be introduced to the West Kent General Hospital.

Middlesbrough.—At a meeting of the Middlesbrough Streets Committee, the deputy town clerk read a letter from the Imperial Tramway Company stating that the directors purposed submitting an application to the Corporation for certain alterations and extensions of the tramway system, together with the reconstruction of the present lines in order to admit of the whole being worked by electricity. Inasmuch as the application would have to be dealt with in due course by the Streets Committee, the directors invited the whole of the members of the committee, together with the town clerk and the borough engineer, to visit Bristol for the purpose of inspecting some of the most recent installations of electric traction which had been in successful operation for close on 12 months under the administration of the directors and officials of the Imperial Tramway Company. Councillor Redmond did not think they ought to take advantage of the courteous and generous offer of the tramway company. Any of them could see what was being done in the direction of tramway traction by electricity without going to Bristol. They could see what was being done at Hartlepool. He proposed that they adopt the system of electric traction. The Chairman said he thought it was rather premature to take any definite action. They should first have the scheme before them. After some discussion it was ultimately resolved to ask the tramway company to submit plans of the scheme they proposed to adopt.

Edinburgh.—The electric light extension is to cost between £60,000 and £70,000. Treasurer M'Crae, in moving the adoption of the Assessment Committee's report at the meeting of the Town Council, said that as the Council had as yet given no decision as to the electric light account surplus, the City Chamberlain, for the purpose of estimating, had to take that surplus into consideration according to the Act of 1879. That surplus and the surplus estimated for the current year gave a seeming advantage of £7,000 odd. He wished to make it clear that the surplus last year on the electric lighting account had been carried forward to the electric lighting of this year, and the Council would be called upon to say what was to be done with that surplus. Although this £7,000 was seemingly a credit they were taking advantage of, he had to state that on the other side they were to receive a sum from the Electric Lighting Committee of £5,900, which was the amount of the several sums paid from the rates on account of the electric light before it was a revenue-producing subject. So that if they took £5,900 and the surplus of £1,596, they were able to pay their way, although the Council should not vote any further sum from the electric lighting to the rates. It might be said that that was cutting it rather fine. He did not think so. Hitherto their estimates had not been exceeded. In fact, they had always had a margin to go upon, and for the last five years at least they had always had a surplus, and he had not the slightest doubt that this year they would also be able to pay their way. The report was adopted.

Wimbledon.—The annual report of the Urban District Council for the year ending March 31 last contains a history of the electric lighting movement from the time when a report on the best means of lighting the district with electricity was obtained from Mr. A. H. Preece, and application was made to the Local Government Board for sanction to a loan of £32,000 for carrying out the work. An enquiry was held by an inspector of the Local Government Board on November 1, 1895, at which the Wimbledon Ratepayers' Association opposed the scheme. After a long delay the Local Government Board, without expressing any opinion on the merits of the scheme, refused to give the sanction until the Council had obtained a renewal of their license from the Board of Trade, or a provisional order, the existing license expiring on October 2, 1896. It was then too late to apply for a provisional order in 1896, and the Board of Trade had decided not to grant any more licenses except under very special conditions. The Board of Trade were therefore asked if they would grant a renewal of the existing license for such a period as would be necessary to enable the Council to obtain a provisional order. They replied that they would grant a renewal of the license for a period not exceeding two years at the expiration of the existing license. The Local Government Board, however, intimated that they would only grant their sanction for the period of the license. This would have been useless under the circumstances, and the matter remained in abeyance pending the decision of the Council as to whether they will apply for a provisional order in 1897. The Council have since decided to apply for the order.

Dover.—At the meeting of the Town Council the Lighting Committee of the Town Ward reported that estimates for the lighting of Biggin-street had been obtained from the electric light company and the gas company, and they asked the Council to decide which system should be adopted, and then to refer the matter back to them to decide the positions, etc., of the lamps. The electric light company tendered to light Biggin-street with nine arc lamps in accordance with the existing agreement at £30 per annum. The gas company tendered to light Biggin-street with 33 incandescent lamps, 30 yards apart, twice the number now existing, at a total cost of £123. 15s. per annum. A memorial was received from all the inhabitants of Cannon-street and Biggin-street, with two or three exceptions, requesting the Council to light the street with electric light. Councillor Mackenzie moved that the memorial should be acceded to and the electric light company's offer be accepted. He believed electricity to be the light of the future for public lighting. Dover was going ahead, and if they were to keep ahead Dover must take the new light for the better illumination of the town. As regards the cost, the difference in such a street between gas and electricity was small. After considerable discussion the motion was put, and carried by six votes to two. It was decided to postpone the alteration of the lamps in Worthington-street until the new lamps of the electric light were seen. The Town Ward Lighting Committee were given the direction of placing of the lamps in Biggin-street.

Unfenced Machinery.—At the North London Police Court on Tuesday the London and Lancashire Electric and General Engineering Company, of Kingsland Green, was summoned before Mr. Paul Taylor for non-compliance with the Factory and Workshops Acts of 1878 and 1895 in not having machinery and gearing on their premises properly fenced. Mr. G. J. L. Blenkinsopp, one of her Majesty's inspectors of factories, prosecuted; and the company made no legal appearance. A clerk was, however, allowed to watch the case on their behalf. Mr. K. H. Garvie, another inspector attached to the Home Office, said that he visited the premises on July 31 and found a gas-engine at work, unfenced, in the workshop. Witness had visited the premises three times within 12 months, and each time he had found engines and gearing unfenced. On the occasion of the last visit witness asked how long the gas-engine had been at work in its present position, and he was told three months. The secretary and the manager of the company had been repeatedly warned of the requirements of the Act, an abstract of which was posted in the factory. Mr. Blenkinsopp said he regarded this as a case of great neglect. The clerk who attended for the company said that the company were waiting to hear what they were required to do. Mr. Paul Taylor said it appeared to be a gross attempt to evade the Act. The company must be taught that they could not set the law at defiance. The full penalty of £10 and costs was imposed. On the application of Mr. Blenkinsopp, the magistrates further made an order for the fencing of the machinery within 14 days.

Electric Transmission of Power Machinery.—The Arniston Coal Company, of Gorebridge, N.B., have contracted with Ernest Scott and Mountain, Limited, electrical and general engineers, Close Works Newcastle, for the supply of an electric pumping plant, for their colliery, of considerable size. The generating machinery consists of: Two horizontal engines with Corliss trip expansion gear, each engine being capable of giving 300 b.h p., with a steam pressure of 120lb. per square inch when running at a speed of 84 revolutions per minute, the steam being supplied by two Lancashire boilers, each 30ft. long by 8ft. diameter, for a working pressure of 140lb. per square inch. The engines drive by rope on to two continuous-current dynamos, each machine giving an output of 200,000 watts at an E.M.F. of 525 volts. These dynamos are placed on sliding bedplates, so that the slack of the belt can be taken up whilst they are running. The current from the dynamo is taken to a dis-

Digitized by Google

tributing switchboard in the engine-room, the switchboard connecting with two pairs of main cables, which run down the shaft to the terminal-box at the pit bottom, in which switches are placed, so that either or both dynamos can feed either circuit, the underground pumping being divided into two separate circuits. The object of placing four cables in the shaft is to prevent any possibility of breakdown through the cables being accidentally damaged, as any pair of cables can, in case of emergency, carry sufficient current to enable the plant to run without stoppage. Underground there are four sets of three throw pumps of Messrs. Scott and Mountain's improved type, with independent interchangeable pump bodies, valve-boxes, suction and delivery branches, and air-vessel, one pump delivering 500 gallons of water per minute against a head of 270ft., along a road to a sump at the bottom of the shaft about 1,200 yards away. At this point a second pump of the same size—viz., to deliver 500 gallons—is placed, and forces to bank against a head of 690ft. Two dip pumps are being provided at present, each delivering 100 gallons per minute against a head of 450ft., but at a future date two additional sets of pumps will be provided. Sufficient capacity in the dynamos and generators has been allowed for the working of the additional pumps, and also for the electric haulage gears and other transmission of power machinery which may be required for the working of the colliery at a later date. The cables down the shaft are heavily armoured, as a protection against mechanical injury, the underground cables being highly insulated.

Southampton.—At the meeting of the Corporation the Electric Lighting Committee reported the receipt of the following sanctions to loans: for the purchase of the undertaking, £21,100 for a period of 15 years; for new buildings, and extension works and mains, £28,900 for 25 years, and for the purchase of additional land, £5,300 for 50 years. The town clerk was instructed to apply to the Local Government Board for an extension from 25 to 30 years for the repayment of the loan of £28,900, and the Finance Committee requested to provide a cheque for £21.100 for the purchase of the undertaking. The committee considered the subject of making arrangements for the taking over of the undertaking and the staff, and resolved that the staff of the electric lighting company be engaged at the same salaries and wages as they were receiving, and subject to the terms of their present engagements; and that Mr. Miles (Mr. Hamilton's clerk) be appointed accountant and collector at a salary of £120 per annum. Alderman Bone proposed the adoption of the report, stating that after waiting a long time they had obtained sanction for the borrowing of the money for the electric light works, and since the receipt of the sanction the sum of £21,100 had been paid over to the electric lighting company, and the works were now in the possession of the Corporation. The committee had no other alternative but to take over the staff, and in time they would be able to see if the officials were such as should be retained. Mr. Miles was acquainted with the work, but he would be subject to Mr. Ramshaw, chief accountant to the Corporation, though he would carry out the calculations and collection for the electric light. The engineer was away, but on his return the committee would take into consideration what extension the present plant was capable of, and also whether they could reduce the price of the current, so that they might induce, if possible, various inhabitants in East-street and other parts, where they hoped to extend it, to take the light. Mr. Batchelor seconded the proposition. Mr. McDonnell complained that they were taking over a large staff without knowing anything of their number, salaries, and the terms of their engagement, and elevating them to the position of Corporation officials. He proposed as an amendment that the matter be referred back to the committee for these particulars to be supplied. Alderman Bone gave particulars as to the wages, the whole of which would be not quite £10 a week. Mr. McDonnell still pressed his amendment, and Mr. Dunsford seconded, as the appointments should not be made without being advertised. After some discussion the amendment was withdrawn, and on a show of hands 28 were for the proposition and 5 against. Mr. Alderman Bone moved, "That as the electric lighting is now in the hands of the Corporation, it be referred to the Estates Committee to take the necessary steps to have the Council-chamber and municipal offices lighted by electricity forthwith." He thought it would be much more comfortable in the Council-chamber and indeed throughout the audit house if gas was superseded by electric light. Alderman Gilbert seconded, and the motion was carried.

Minster.—At the meeting of the Isle of Thanet Board of Guardians the following important report was received from the Lighting Committee: "The committee appointed to enquire into the question of lighting beg to report as follows: The amount paid last year for gas was £421, to which must be added for new burners, etc., about £20, and deducted for gas used in cooking nearly £23, leaving for lighting £419. But as the first quarter of 1895 was, owing to bad weather, an exceptionally heavy one, the committee consider £400 per annum a fair estimate to make for lighting the union under present conditions. This undoubtedly is too heavy an expenditure for the light obtained. A certain waste appears to the committee to have arisen from want of care in leaving lights on unnecessarily, and they recommend a stricter supervision in this respect. They also think a further check might be obtained by a daily record being kept of the reading of each meter. This waste, however, goes a very little way in explaining the heavy expenditure. The chief cause is to be found in the high price charged for the gas and its inferior quality. The illuminating power is low, and the fumes thrown off are offensive and insanitary. To a limited extent incandescent burners have been fitted in the house, and the committee had under consideration the general adoption of this system, but the reports from your officers do not encourage this. The impure condition of the gas tends to clog the incandescent burners, and although, with care, where the lights are under the direct control of your officers, this difficulty may be overcome, in other parts of the union where they have been tried the life of the mantles has been so short that their general adoption would entail considerable addition to the annual cost of lighting. Acting under the authority of the Board, the committee have obtained reports from three separate firms of electrical engineers and contractors on electric lighting. These reports are submitted herewith. Summarised they are as follows: Harraps'—installation £1,550, annual cost £270, lights 410; Glover's—installation £1,484, annual cost £200, lights 383; Mackie—installation £1,130, annual cost £287, lights 368. Messrs. Glover make no allowance for depreciation. The existing number of gas-burners is 310, and the annual cost of gas £400. It is therefore clear, assuming the above figures to be correct, that on either estimate a large saving would be effected by the adoption of the electric light. The committee do not hide from themselves that all such estimates—especially in regard to the annual cost—must be accepted with reserve, but they have assured themselves that the gentlemen consulted are practical and competent men, and that their estimates have been drawn with care, and guided by their reports the committee have arrived at the conclusion that under the present conditions of the supply of gas, the electric light, both from an economical and sanitary point of view, is preferable." After a long discussion it was decided, on the motion of Mr. Matthews, seconded by Mr. Hermitage, that the consideration of the subject stand over until the clerk has endeavoured to obtain some information on the question from other institutions.

Torquay.—The Town Council intend to proceed with their electric lighting works as speedily as possible. It is only the other day that the Local Government Board signified their sanction of the scheme and the proposal to borrow £23,000, but the general conditions and specifications for tendering have already been agreed upon, and will receive the approval of the Council next week. In the general conditions it is laid down that the work must be completed within six months of the date of the contract. Following is a general outline of the works: There are to be three boilers of the water-tube or modified marine type, capable of working at a pressure of 150lb. per square inch; two Worthington duplex feed pumps, and one of Druitt Halpin's feed storage cylinders, 6ft. in diameter and 20ft. in length. The engine-house plant is to include three high-speed compound engines, preferably of the three-crank single-acting type, each capable of driving a 125-kilowatt alternator as a maximum at a pressure of 130lb. in steam-chest. The engines are to have all the working parts closed in, and are to be arranged for driving alternators direct. The speed shall not exceed 450 revolutions per minute. One engine of the same type, capable of driving a 25-kilowatt alternator at about 500 revolutions per minute, is to be provided for day load. "The engines must run at all loads without perceptible noise or vibration." There are to be three alternators, one to be coupled direct to each of the larger engines, and each to be capable of delivering to the external circuit 125 kilowatts at an E.M.F. of 2,000 volts, and of maintaining this load without strain for an indefinite period at a speed not exceeding 450 revolutions per minute. The main foundations for engines and alternators are to consist of a block of cement concrete solid, with the exception of any necessary trenches for pipes, etc., and to be at least 8ft. thick. Upon the concrete bottom the contractor is to place a layer of hairfelt, of such a depth that the weight of foundation shall not compress it to less than 2in. in thickness. Above this, and under concrete, must be placed two layers of good roofing felt, so arranged as to break joint. There will be five feeder circuits and one street-lighting incandescent circuit, all of the concentric type. Feeders and street lighting mains are to be laid in the following thoroughfares: Beacon-terrace and Victoria-parade, Strand, Fleet-street to town hall, Lower Union-street and part of Higher Union-street to Torbay Hospital, Higher Union-street from hospital to Torre Station, Torbay-road to Belgrave-road, Torwood-street. Feeders only are to be provided in the following: Torwood-street, Babbacombe and Stitchill roads, part of Lower Warberry-road, Higher Warberry-road, Meadfoot-lane, Parkhill-road and part of Middle Woodfield-road, Ridgway-road, Higher Erith-road, Meadfoot-road, Upper Lincombe road, and Belgrave-road. Arc lamp circuits are to be laid in Beacon-terrace, Victoria-parade, part of Torwood-street, Strand and Fleet and Union streets to Tor Station, Market-street to Ellacombe-green, Torbay-road to borough boundary, the Pier. Low-tensions mains are to be laid in Beacon-terrace and Victoria-parade, Strand, Fleet-street to Pavilion Hotel, and on to Tor Station, Torwood-street, Torbay-road to Cumper's Hotel, part of Park-road and Belgrave-road. Three extra ways are to be laid in stoneware casing in Beacon-terrace, Victoria-parade, and Strand; and two extra ways in Fleet-street to town hall, and Union-street to Torbay Hospital. The conductor is to be composed of copper having a conductivity of not less than 100 per cent. of Matthiessen's standard. All the cables are to be stranded, and each strand to be coated with pure tin. The conductor must be covered with fibrous or other approved material capable of absorbing an insulating oil or compound, and the insulation must be protected with a covering of lead, upon which will be two layers of strong tape or braid, so as to withstand moisture. The cables will all be laid 2½ft. deep in Doulton or other stoneware conduits, or, where several are in the same trench, in wooden troughing filled with bitumen. There are to be 70 arc lamps for street-lighting, upon ornamental lamp-posts of such a height that the globe of lamp shall be about 20ft. from the ground Thirty-kilowatt transformers are to be placed in pits at the junction of Fleet-street with the Strand; and 20-kilowatt transformers are to be

Digitized by Google

placed outside the Queen's Hotel, near the Town Hall, and 70 yards above Market-street; while 10 kilowatt will be in generating station, opposite Upton Church, end of Vansittart-road, near Clarence Hotel, top of Market street, and two in Belgrave-road. Mr. Garrett, the borough surveyor, will erect the chimney shaft at the central station, and the coal-stores near the Bath Saloons.

PROVISIONAL PATENTS, 1896.

SEPTEMBER 21.

64a. **Improvements in and relating to electric or other tramways** Francis Krizik, 433, Strand, London (Date claimed under Patents Rule 19, January 1, 1896.) (Complete specification.)

64b. **Improvements in or relating to electric tramways or railways.** Francis Krizik, 433, Strand, London (Date claimed under Patents Rule 19, January 1, 1896.) (Complete specification.)

20864. **Improvements in and connected with automatic and other electric meters.** Francis Malger Staunton, 77, Chancery-lane, London.

20881. **Improved means for jointing and protecting electric conductors specially applicable for use in the wiring of buildings** Victor George Middleton, 46, Lincoln's-inn fields, London.

20902. **Improved mechanism for electric arc lamps** P. R Jackson and Co, Limited, and Louis Carl Henry Mensing, 166, Fleet-street, London. (Complete specification.)

SEPTEMBER 22.

20961 **Improvements in incandescent electric lamps.** John Thomas Lister and William Selah Chamberlain, 75, Chancery-lane, London. (Complete specification.)

20962. **Improvements in or connected with electric railways.** James Thomas Rossiter and the British Electric Traction (Pioneer) Company, Limited, Norfolk House, Norfolk street Strand, London.

20963. **Improvements in switches for use in connection with electric railways** James Thomas Rossiter and the British Electric Traction (Pioneer) Company, Limited, Norfolk House, Norfolk-street. Strand London.

20964. **Improvements in current collectors for electric railways** James Thomas Rossiter and the British Electric Traction (Pioneer) Company, Limited, Norfolk House, Norfolk-street, Strand, London.

20966. **An attachment for electric incandescence lamps** Forest William Dunlap and John Robert Quain, 60, Queen Victoria-street, London.

20969. **Improvements in the armourings or coverings of electric cables** Henry Edmunds, 47, Lincoln's-inn-fields London.

20981. **Improvements relating to the production, regulation, and utilisation of electric currents of high frequency, and to apparatus therefor.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Nikola Tesla, United States.) (Complete specification.)

20984. **Improvements in electric brakes.** The British Thomson-Houston Company, Limited, 70, Chancery lane, London. (Alexander F. Macdonald, United States.) (Complete specification.)

21003. **Improvements in speed-retarding appliances for electricity meters.** Reginald Page Wilson, 191, Fleet-street, London.

21009. **Improvements in construction of low-tension dynamo-electric machinery.** Francis Edward Elmore, 28, Southampton buildings, Chancery-lane, London.

21027. **Improvements in electrolytic apparatus.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (The Aluminium Industrie Aktien Gesellschaft, Switzerland)

SEPTEMBER 23.

21055. **Improvements in electric fittings.** Edward Jesse Piper, 34, Victoria-street, Westminster, London.

21116. **Improvements in ticket-issuing apparatus for the electrical staff instruments on single lines of railways** John Patrick O'Donnell, 70, Palace-chambers, Westminster, London. (John William Wainwright Hopkins, Argentine Republic.)

SEPTEMBER 24.

21128. **Improvements in metallic posts for fencing telegraph and similar purposes.** William Tozer, 95, Finsbury-pavement, London.

21147. **Improvements in or connected with coin-freed or actuated electricity meters.** George Ellis and George Hinde Nisbett, 15, Water-street, Liverpool.

SEPTEMBER 25.

21236. **An electric regulator.** Walter Emmott, 1, South-parade, Halifax.

21273. **Improvements in or relating to electric storage batteries.** John Evelyn Liardet, 9, Warwick-court, Gray's-inn, London.

21293. **Improvements in electrical doorbolts.** Samuel Flood Page, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SEPTEMBER 26.

21340 **Insulated conductors and improved collectors for electric tramways** Robert Henry Smith, 124, Hagley-road, Birmingham.

21365 **Improvements in electric meters.** Emanuel Bergmann, 18, Buckingham-street, Strand, London.

21380. **Improvements in apparatus for supplying electricity to electrically-propelled railway and tramway vehicles.** William Lloyd Wise. 46, Lincoln's-inn-fields, London. (Alfredo Diatto, Italy)

SPECIFICATIONS PUBLISHED.

1895.

16557 **Electro-deposition of gold and silver.** Andreoli.

18487 **Electrolytic manufacture of ferro-manganese, ferro-chrome, ferro-aluminium, ferro-nickel, and other "alloys" having an iron base** Heibling.

18583. **Means for making electric connection between lengths of rail and the like.** Edmunds.

19272 **Steering of electric or steam carriages, cycles, bath chairs, or other like vehicles** Kesterton.

20335. **Electric arc lamps.** Collinson.

20636. **Telephone instruments.** Truss.

20681. **Ventilation of transformer-boxes, road and junction boxes, conduits, and the like, used in the distribution of electrical energy.** Penson.

20696. **Electric switches.** Nalder and Soames.

20821 **Reflector for electric arc lamps** Fabris.

21433. **Holders or carriers of electrical incandescent or glow lamps** Evered.

NOTES.

The Junior Engineers.—The annual general meeting of the Institution of Junior Engineers will take place at the Westminster Palace Hotel on Friday, October 16, at 8 p.m.

Publication Received.—We have to acknowledge the receipt from Messrs. Witherby and Co., 326, High Holborn, W., of "Lean's Royal Navy List." This is published quarterly, and the present number is the seventy-sixth.

Self-Propelled Traffic Association.—A branch of the Self-Propelled Traffic Association has been formed at Liverpool with Lord Derby as president. Sir David Salomons is to deliver the inaugural address of the branch some time during the month.

Telegrams to Ecuador.—Communication over the Ecuadorian land lines appears to have been in a bad way for a long time. It is now announced that telegraphic communication with Guayaquil is interrupted, owing to a great fire which has occurred there.

The Value of v.—Mr. D. Hurmuzescu has been making a new determination of the ratio v connecting the electrostatic and electromagnetic units. According to a communication to the French Société de Physique, his result is a value between 30002×10^6 and 30005×10^6 cm/sec.

The Midland Engineers.—The general meeting of the Chesterfield and Midland Counties Institution of Engineers will be held at University College, Nottingham, on October 17, at 3 p.m. Members likely to attend the proposed meeting in Canada next autumn are asked to send in their names to the secretary.

Guttapercha.—According to the *Revue Industrielle*, Mr. Sarrazin has found a new source of guttapercha in the French Soudan. It is a creeping plant, the botanical name of which is given as *lythophilum album*, and is found growing in the Baleya and Sankaran districts. The possible supply from this source is put at about 100 tons per annum, if it could all be utilised.

Changing the Frequency.—A device for changing the frequency of an alternating current at the place of consumption (Gutmann's method) has been described in the New York *Electrical Engineer*. An armature wound like a Gramme ring has connections at symmetrical points and revolves in a field produced by the alternating current. The current generated in any one of the sections of the armature will then have a frequency bearing a definite ratio to that of the current exciting the field.

Accident.—Last Friday evening Mr. John H. Whittaker, electrical engineer, of Dudley, was admitted into the Guest Hospital suffering from a severe dislocation to the forearm and injuries to the face. Mr. Whittaker, it is stated, while superintending some operations in connection with the completion of the laying down of an electric lighting plant, got the sleeve of his coat caught between the driving-belt and the dynamo pulley, and appears to have had a narrow escape of receiving more serious injury.

The Cost of Calcium Carbide.—The sanguine estimates as to the selling price of calcum carbide that have at various times been put forward by the advocates of acetylene as an illuminant do not appear to be altogether pleasing to some of the companies that make it. The Neuhausen Company, for instance, has written to the *Zeitschrift für Beleuchtungswesen* protesting against estimates to the effect that its present price of about £20 per ton for the carbide may be reduced to nearly £9. Some reduction, it is said, may possibly be effected shortly, but nothing of this wholesale character.

Lighthouse Communication.—The "Smalls" lighthouse, situated 20 miles from the mainland at the entrance of St. George's Channel, and within signal distance of the Bristol Channel, was last week connected by cable with the mainland. The present intention is to enable the lightkeepers, in case of shipwreck, casualties, or distress, to give information for the use of the lifeboat and to the coastguard, but it is hoped that the postal authorities may be induced to also allow a mercantile signal station to be ultimately included.

Warning.—The Commissioner of Police has warned London householders against a thief who gains access to houses on the pretence of inspecting telegraph or electric light wires. This man is wanted by the police for numerous offences. He is usually dressed like a workman, and carries a coil of wire. As, however, he most probably looks at a daily paper, it is quite possible that he may discard the coil of wire for something else after this. The make-up and accessory wire was not very well chosen, but it would appear to have been good enough.

Electrical Exhibition.—It is stated in the *Newcastle Daily Chronicle* that there is to be an electrical exhibition next February at Newcastle-on-Tyne. "There being no permanent building adapted for showing heavy machinery and machinery in motion, a site on Pandon Dene has been secured, on which special temporary buildings will be erected, and these will be so arranged as to meet the requirements of the exhibits referred to. It is intended to be strictly an exhibition, and in no way an organisation for the sale of goods." The exhibition is a private speculation.

The Perils of Cable-Laying.—The Strand has been in a considerable mess lately, the responsibility for which must be apportioned between the road authorities, the electric lighting companies, and the clerk of the weather. One gentleman in Norfolk-street, by way of enforcing his views that even in the Strand quiet should be found at three o'clock in the morning, took a shot in the direction of the electric light workmen with a revolver. Subsequently, in an interview with Mr. Vaughan at Bow-street, he admitted that the protest was unjustifiably forcible. Mr. Vaughan thought 40s. would meet the case.

Obituary.—The death has been announced, at the age of 88, of the widow of the late Mr. Charles Darwin, the illustrious naturalist. Mrs. Darwin was the daughter of Darwin's uncle, Josiah Wedgwood, and the granddaughter of the founder of the Etruria works. The heredity of intellect is illustrated by the fact that the surviving children of the marriage include Mr. George Howard Darwin, F.R.S., Plumian professor of astronomy at Cambridge; Mr. Francis Darwin, F.R S., university reader in botany at Cambridge; and Leonard Darwin, late member for the Lichfield division of Staffordshire.

Submarine Telegraph Memorial.—The committee which is promoting a memorial of the foundation of submarine telegraphy held a meeting on Tuesday. The Earl of Selborne presided. Lord Kelvin was not present, but it was stated that his views as to the form that the memorial should take was that the bulk of the fund should be applied to the foundation of scholarships in connection with electrical science in London and Glasgow. A letter was read from Prof. Silvanus Thompson suggesting the application of a portion of the memorial fund to the erection of a permanent home for the Institution of Electrical Engineers.

Conductivity of Iron.—The result of some researches of Dr. Ebeling made at the Berlin Reichsanstalt were given some time ago in the *Zeitschrift für Instrumentenkunde*. He endeavoured to find whether magnetic heterogeneity could be determined by the electric conductivity. A constant

Digitized by Google

current was sent through sample bars and the loss in voltage measured at fixed intervals along the bar. Those bars which had small differences in their magnetic qualities also had small differences in their electric conductivity, but the converse that homogeneous magnetic materials have an even conductivity had exceptions. This, however, might be due to mechanical faults in the material.

The First Under-Sea Telegraph.—The proposal for a memorial of the establishment of submarine telegraphy has naturally brought about some discussion as to who was the first to do it. Mr. F. E. Baines, formerly Surveyor-General of Telegraphs, has written to the *Times* claiming that the absolute first, "if not the true originator of, submarine telegraphs was the late Mr. C. V. Walker, F.R.A.S., telegraph engineer of the South-Eastern Railway. Mr. Walker, on January 10, 1849, carried out to sea from Folkestone two miles of covered wire, and through the insulated conducter thus submerged held telegraphic conversation with his chairman in London from the deck of a vessel afloat."

Motorcarts.—Of the 32 motorcarts and motor cycles that started in the race to Marseilles, 11 got back to Paris last Saturday. Three of these were tricycles. Until the time allowances have been reckoned up no one quite knows which is the winner, and just at present no one particularly cares. Fireworks, illuminations, pine trees without roots, other trees provided with satinette flowers and artificial fruit to remedy the obstinacy of Nature, that will not change her laws even in honour of the visit of a Czar to a Republic, occupy all that is left of Parisian attention. Here in England the Motorcar Club has changed the date of its procession of cars to Brighton from November 14 to October 24. As the new Act will not then be in force, it is to be assumed that the police have been—arranged with.

Scientific Education.—The controversy—if it can be called a controversy where one side only has spoken—in the *Times* on scientific education appears to have drawn to a close. There has, indeed, been one more letter from Sir Philip Magnus, but it contained little new. Sir Matthew White Ridley spoke upon the subject at the opening of the session of the Durham College of Science at Newcastle. One need not reproduce his speech, for unfortunately a Home Secretary need not be a person of any authority in scientific matters. He, however, threw out hopes of more grants to the university colleges of science. The subject has in general proved a mine of wealth to the unfortunate individuals that have to make speeches at the opening of schools and institutes, but the practical result seems to be that matters will be much as before.

Electric Work at Johannesburg.—A description originally appearing in the *Zeitschrift des Vereins Deutscher Ingenieure* supplies some further particulars as to the power transmission line erected by Messrs. Siemens and Halske for the Rand Central Electric Company. The buildings are chiefly in corrugated iron. Four triple-expansion engines of 1,200 h.p. each, of the Sächsische Maschinenfabrik, Chemnitz, will be coupled with Siemens's polyphase generators. The boilers are of the water-tube type. The generators are to run at 100 revolutions. The voltage will be transformed up to 10,000 volts, and transmitted by overhead lines for a total distance of 28 miles; the power station, which is at Brakpan being some distance from the nearest end of the field to be exploited for the present. A start is expected to be made very shortly.

Trade Exhibitions at Islington.—The opening of a series of trade exhibitions to be held at the Agricultural Hall, Islington, was the occasion of a luncheon on Friday last. Mr. Stanley Machin presided, and a remarkable feature of the toast list was that most of the speaking was done by the Press. However, they redressed the balance, which does not usually swing in that direction, by having afterwards quite a quantity of speeches which were not in the programme. The present exhibition relates to grocery; the turn of electricity and electrical fittings will not come till next August. But even in a grocery exhibition it is not safe to be certain that something electrical will not be found. In this case it was a dodge in the connecting up of electric bells, which has been brought out by Messrs. Jones and Collier, of Dartmouth, in view of the exigencies of shop doors, but which might easily have a much wider application. The principle is that instead of the bell-push completing the circuit directly, it sets a chain pendulum swinging, which makes a contact at every vibration. One push, therefore, gives a succession of "strokes" which continue as long as the pendulum keeps on swinging. It is not known whether it has occurred to the inventors, but it is evident that if there were two or more calls on one bell and battery simply varying the lengths of the pendulums would give an easy means of indicating which circuit was calling. Our readers are not specially interested in grocery, but in view of next August we looked round the exhibition to see how things were done, and the arrangements appeared excellent.

A Welsh Thunderstorm.—If we may believe the *Daily News*—it is no mere local print which is responsible for the report—curious things happen in Wales after thunderstorms have been about. On Monday, "the Druids Temperance Hotel at Redruth was almost entirely destroyed by fire. The manager (Mr. Paul) was awakened about half-past five in the morning by the ringing of the electric bells in the house." After details of damage, it is added, "The cause of the outbreak is uncertain, but it is believed that a severe thunderstorm which passed over the town during the night had some connection with it, and the ringing of the electric bells is pointed to as supporting the theory that the electric fluid may have originated the fire." Whether this is believed in Bouverie-street, or only in Redruth, is not absolutely clear. It would no doubt have been a considerate act on the part of the thunderstorm after having done the mischief to give the alarm in this way, but it is just possible that an electric bell fitter—we will not say an electrician—might imagine a simpler way in which in the course of a fire the bell circuit would get completed and the bells start ringing. But then this particular storm was a remarkable one in other ways "The thunderstorm was so severe that a police constable was carried by some agency which he is unable to explain a distance of 30ft. from where he had been standing" Making all due allowance for a natural professional bias against believing unnecessary evil of electricity, we are still more inclined to think that it was a combination of wind and fright that moved that policeman rather than electrostatic attraction.

Meters in America.—In the course of an article in the *American Electrician* on the subject of electric meters, Mr. Thomas Duncan makes some curious observations Apparently the American customer can be made to understand what an ampere is, but a watt is beyond his intellectual grasp, or it is thought so. But there seems to be a preference for mere "lamp-hour" instruments. From the central-station point of view that would be quite comprehensible. The complete paragraph runs as follows: "If the meter be a lamp-hour instrument, the chances for checking by the consumer are without doubt the simplest and most easily understood. If he entertains any doubt

Digitized by Google

in his mind as to its accuracy of operation, it is only necessary to keep a record of the number of lamps used during an evening and their time of use, or the number of hours they have been burning, when the product of these two quantities will give the reading of the meter. If it be an ampere-hour meter, it becomes necessary that he be made acquainted with what is meant by the unit 'ampere,' which can without much difficulty be explained to him so as to be intelligently understood. When a wattmeter is employed for measuring the energy, it is not quite so easy to make him understand what he is paying for, and in many cases a consumer has a disposition not to pay for anything he does not quite understand. This, of course, is natural, but yet I have heard central-station men express a desire for wattmeters, since the mere fact of their customers not understanding what a watt-hour is makes them less liable to check up the readings of the meter, as is easily accomplished with a lamp-hour meter."

Electric Locomotives.—It has been stated that an electric locomotive is to be tried experimentally on the lines of the Manhattan Railway Company, New York, in which the engine will carry a secondary battery, charged by current obtained from a third rail. The charge thus obtained will enable runs of 15 to 20 miles to be made over rails not electrically equipped. If experience in accumulator traction goes for anything, the advantage of this will hardly pay for the increased cost and the loss due to the double conversion. A locomotive of altogether a different type is described in the *Scientific American.* It is one constructed by the Baldwin Locomotive Works and the Westinghouse Electric Manufacturing Company. The locomotive is for the use of the Crozer Coal and Coke Company at Elkhorn, West Virginia, in the Pocohontas coalfield. It has six coupled wheels, and is capable of drawing 40 loaded cars up a 2 per cent. incline at a rate of six miles per hour, developing a draw-bar pull of 10,000lb. The track gauge is 44in., and the rails weighs 40lb. per yard. The locomotive will pass through an opening 6ft. 11in. high above the rails, 10ft. wide at bottom and 8ft. wide at top. There are two 100-h.p. Westinghouse motors, which are series wound, and may be operated either in series or parallel. The series arrangement is used for slow speeds, and the parallel for higher speeds. The motors are connected to driving axles by double-reduction gears. The average speed of the locomotive with the motors in parallel is stated to be six to eight miles per hour. The current is taken from an overhead line by a trolley arm, and the voltage is about 500.

Magnetic Units.—The New York *Electrical World* is apparently greatly disappointed that the Geneva Electrical Congress has not resulted in the adoption of the system of units advocated by the American Institute of Electrical Engineers. "As to the incomplete and hybrid set of units," says our contemporary, which were adopted by the British Association, "no apparent reason suggests itself for such action other than an attempt to antagonise as effectually as possible the desired aims of the American body." Without discussing the merits of the question one way or the other, it is perfectly certain that no thought of anything of the kind ever entered the minds of anyone on this side of the water. We are then told quite straightly what we are to do on this side of the Atlantic. "It remains for the British Association, a universally respected body, to reconsider the vote of last year, and to either propose magnetic units having some claim for superiority over those provisorily adopted by the American Institute of Electrical Engineers, or adopt the units which the latter has proposed. The aim to be strived for is universal agreement." Quite so; but in order to secure that, the authority of a body would be required which is much more truly representative of electrical science throughout the world than the Geneva meeting could claim to be. And although in some branches of electrical engineering the Americans have got the start of the rest of the world, so that we may reasonably go there to see what things may be done, and what dangers must be avoided, they have by no means such a pre-eminence in the theoretical part of the subject as would enable them to decide between the fancies of French and German experts, even if Great Britain stood neutral in the matter.

A Narrow Escape.—The following shows the way in which accidents may happen in America. It will be seen in the sequel that it was a barge that was smashed and not an electric tramcar, but it might very well have been otherwise. The Americans have a perfect right to fix their own standard of safety or unsafety where they think best, and work their railroads and tramways how they please. They may tell us it is no concern of ours; and some of them do pretty plainly. But in a way it is, for whenever anything goes wrong and makes mischief in America, it is used to discredit the introduction of electric traction in this country. The *Western Electrician* describes the occurrence to which we refer thus: "A curious accident occurred in Chicago the other day by which a trolley car was hoisted several feet in the air on the big hoist bridge at Halsted-street over the south branch of the Chicago River. The engineer saw a barge coming, or was notified by a policeman to that effect—the accounts are conflicting—and hoisted the bridge without waiting for the usual signal from the bridge-tender's tower. An electric car was on the structure at the time and was lifted with it to a distance variously stated at from 10ft. to 30ft. The motorman stuck to his post, but the passengers were alarmed and scrambled from their seats. The bridge-tender immediately sounded the signal to lower the bridge. This signal was obeyed, and this movement nearly crushed the barge, which had not cleared the bridge. Finally the boat got through, the bridge was restored to the street level, and the car resumed its strangely interrupted journey without injury to anyone. The fault is attributed to the engineer in acting without orders. The Halsted-street Bridge, which is of rather unusual construction, has attracted much attention from engineers. It has a direct vertical hoist said to be 212ft."

Municipal Management.—The *Street Railway Journal* likes the English and European ways of managing municipal matters better than the American one. In other words, the permanent official is better to work up to than the mere party nominee. The former implies a certain amount of "red-tape" and formality, yet under the European system "it is possible to push through great municipal improvements at an expense much less than that which is found necessary" in the United States. The benefits of a foreign system are often exaggerated and its defects not observed, but our contemporary is probably not far wrong in its conclusion that America has much to learn from Europe in the matter of the business management of municipalities. "Through centuries of experiment and by means of mistakes as glaring as those now committed in American cities there has been evolved in Great Britain and most of the Continental countries a system of municipal administration which is certainly economical and efficient in most cases, and is certainly far more scientific in principle than that found in general in this country. The especial feature of the European system is the selection of trained engineers of the highest character for the principal departments where engineering ability is required

Digitized by Google

and for the higher positions, even up to the mayoralty, of men who have not only proven themselves good men of business, but who are fitted by special experience for the positions which they occupy. An administrative corps of this character is far superior to one selected for political reasons or whose members are mere accidents of the hour. Another point of advantage in the European system is the close interdependence of the various departments of a city, district and national government." But sometimes there is less difference between our local bodies and those of America than our contemporary imagines.

Rontgen Ray Work.—In the course of his inaugural address to the Pharmaceutical Society of Ireland Prof. C. R. Tichborne urged that pharmacists (in England, less accurately, we call them chemists) should make the taking of Röntgen photographs a part of their business. If the art became essential to successful surgeons it was evident that it must be at the disposal of every practising surgeon, where-ever he found himself and whatever the surrounding circumstances might be. But to suppose that every busy surgeon in country towns would maintain battery, coil, tubes, and photographic paraphernalia in working order was not at all likely. He might for a brief space, but when the emergency came he would find that he had not got his apparatus in order. Here the pharmaceutical chemist might step in, and for a moderate fee give him the revelation of the particular part he wants. Prof. Tichborne doubtless knows more about Irish surgeons than we do, but on the face of it we do not see why a surgeon should be less likely to have his tools ready when wanted than a chemist. Moreover, the latter would have to leave his shop to go to the patient, a matter to be considered in the fee and expenses. It is stated in a letter to the *Scientific American* that a very fair cryptoscope screen for Röntgen ray experiments can be made by coating a piece of pasteboard with prepared glue and sifting on a coating of common zinc white (oxide of zinc), which can be obtained very cheaply at any paint shop. As potassium platino-cyanide is never likely to be very cheap and the proper quality of calcium tungstate is not always obtainable in an instant, the suggestion may be worth testing by anyone who does not use a fluorescent screen habitually, but might find the occasional use of it helpful as a preliminary to exposing the sensitised plate. The behaviour of different fluorescing materials, however, depends very much on the current and tube used.

Society of Engineers.—At a meeting of the Society of Engineers, held at the Royal United Service Institution, Whitehall, last Monday evening, a paper was read by Mr. William G. Wales, A.M.I.C.E., on "Discharging and Storing Grain." Having drawn attention to the certain though irregular diminution of home-grown wheat in the United Kingdom, and to the steadily increasing dependance of the English nation upon external sources of supply, Mr. Wales stated that the adoption of grain-discharging machinery had not been very great considering the growth of the imported grain trade during the last quarter of a century, but referred to London and Liverpool as being the two great grain centres where the most modern improvements in this class of machinery were to be seen. Reviewing the various systems of discharging grain, the author first mentioned that carried out by means of a crane and a Priestman bucket or tub, and explained that this system was often used in England on account of the cranes being able to discharge grain in bags, or ordinary merchandise as well as grain in bulk. He next discussed the various kinds of grain elevators, pointing out that their duty was to dredge the grain from the hold of the ship, and to raise it some 20ft. above the quay. These are roughly divided into floating, fixed, and portable elevators. The use of a conveyor band for carrying the grain from the elevator into a warehouse was also referred to. Fixed elevators, which are generally mounted on derrick arms, had been made in this country large enough to discharge grain at the rate of 100 tons per hour, but they are more often only used for discharging grain in barges. Portable elevators were next discussed, and the author then made a few remarks on raising grain by means of compressed air and by suction. Apart from the first cost of these systems, their advantages were shown to be great, as all trimming of the grain in the hold of the ship was dispensed with. The paper concluded with a few remarks on the machinery for distributing grain in warehouses, and also on the respective merits of silos and floor granaries, and also their cost.

Telephones and Tramlines.—What with the British Association and other matters, the Geneva Electrical Congress has almost been forgotten by this time in this country. A somewhat longer reference than the exigencies of space allowed us to give at the time may, however, be made to the report of Dr. Wietlisbach, of Berne, to the congress on the subject of the disturbances in telephone lines produced by the working of electric trams. Obviously the first thing necessary is to find the principal seat or seats of the disturbing influence. A mere steady leakage of current would not affect a telephone; the cause of the noise might be sought in irregularities of contact with the rails (particularly if these are dirty) or with the trolley wire, or, again, it may be the motor might be in fault. It appears that the last supposition is in the main the correct one, for experiments showed that if the motor was replaced by a resistance, and the car run down an incline, the noise ceased, but if the car was lifted and the motor ran, the car remaining stationary, the disturbances continued. The conclusions arrived at by the congress—which for obvious reasons represent mainly German experience—are, briefly, that telephone lines can be protected sufficiently well against heavy currents by abandoning earth returns and using metallic circuits, and the heavy-current circuits should be so insulated and so placed with regard to telephone circuits that the currents passing to earth and the induction effects are reduced to a sufficiently small amount. For earthed circuits, like those for railways, the outgoing line and the apparatus connected with it should be well insulated. There should be insulated return wires, and, if necessary, there might be small "booster" dynamos in those circuits. The rails should be well bonded, transversely connected, and have special return feeders, and the motors should be so constructed as to produce as little undulation of the current as possible. At overhead crossings the telephone lines may be sufficiently protected with fuses when the voltage does not exceed 750, but with a higher voltage the heavy-current wires should be protected with guard wires which are well earthed, and have their earth connections tested continually.

Electric Railways.—The French Society of Civil Engineers in its *Bulletin* has published what is practically a treatise by Mr. E. de Marchena on electric railways. Mr. de Marchena reviews what has been done in tramway work, giving especial attention to American practice, and then goes on to railway work proper. The conclusion of the survey is that in the existing state of the electrical engineering industry the conversion of the French railways into electric lines would be perfectly possible, and that the expense of the work would be small in comparison with the amount of capital already sunk in the lines. The actual sum is put at something over £2,000 a mile. Mr. de Marchena, however, considers that the increased receipts and the reduction in working expenses which might be reasonably

Digitized by Google

expected to follow the adoption of electric traction would more than cover the cost of interest and sinking fund on the capital necessary for the transformation, so that it would be an advantageous operation from a financial point of view. In a matter of this kind, where there is little or no past experience to go upon, probably no two men will bring out exactly the same estimate, and it must not be forgotten that Mr. de Marchena considers feasible the employment of current at a much higher voltage than has hitherto been used in tramway work. "It is well to remark," he says, "that since the introduction of electric traction there has been a continual tendency to increase the pressure. It was at first 200 to 300 volts, then 550 to 600, and now, on the Baltimore and Nantasket line, it has been carried to 1,700 volts." "Why," he asks, "must we stop at that? What prevents us going to 1,000, 2,000, or 3,000 volts?" The considerations of public safety are, he argues, quite different on a fenced railway, to which the general public has no access, from those which obtain on an ordinary street tramway, and the case of a broken wire can be met by the use of automatic circuit breakers. The continuous-current motor for these high tensions is a matter of more difficulty, but the author thinks that at 1,000 to 1,200 volts "the difficulty would not be very great." The saving in copper is obvious, but with every deference to Mr. de Marchena, a line to take a trolley is not quite the same thing as a power transmission line.

A Railway Proposal.—The Metropolitan Railway runs about as many trains as is possible, and at certain times of the day at any rate these trains are as full as they will hold; yet the dividend is not exactly of a satisfying character to the ordinary shareholders. On the other hand, it is useless to endeavour to get more traffic on the suburban branches than the line can carry into the City. To meet this state of things, it has been stated by the *Financial Times* that a syndicate has brought before the directors a plan for an electric railway from the City to Earl's Court below the existing line. It is added that "the members of the syndicate and their friends are said together to control over £1,000,000 of stock; and, naturally, when groups interested to this amount in so small a line as the District bring forward a scheme that, on paper, promises so much at so small a cost, the directors have little choice except to give careful attention to the matter. For £800,000, the syndicate tells us, we can have a brand new line, with an express service between the Mansion House and Earl's Court, two intermediate stopping-places being provided at Victoria and Charing Cross. Moreover, the syndicate is willing to pay all preliminary expenses of enquiry, and, in addition, the members of it are prepared to provide the money necessary for its construction, subject to a guaranteed interest to be fixed between 4 and 5 per cent." If we understand it correctly, it is intended to keep the present line for the all-round and local traffic, while the suburban trains would change their steam for electric locomotives at Earl's Court and run express by the lower line to the City. There would be many obvious advantages in this, and though immediately underneath an existing tunnel is not the cheapest place to build another tunnel, it must be remembered that by taking this course there is no land to be paid for, a consideration which in London may easily be paramount to all others. The position of the proposed additional lines makes the adoption of electric traction a necessity. Should the scheme ever be carried out there will be an opening for some contrivance in the way of an automatic signalling apparatus, as it is evident that although there are only two stations the line would require to be divided into more than three block sections on the ordinary plan. The scheme has, however, been at present discussed rather from a financial than an engineering point of view, and it is quite uncertain what form it may ultimately take. Should a later suggestion be adopted—namely, to suppress the station at Victoria and make all passengers change and go down lifts into the new electric line at Earl's Court—much of the convenience offered by the line would be lost.

Ether Waves.—The interchange of views at the British Association on the theory of the Röntgen radiations formed the subject of an article in our columns last week. One or two points, however, may be referred to. In the first place, it should be remembered that the Helmholtz theory of dispersion brought forward by Prof. J. J. Thomson is not a theory of the radiations, but only an illustration of how if the wave-length is supposed short enough there may be no refraction. Even if the particular and very specific relation between the luminiferous medium and the molecules assumed in that hypothesis were in a general way the true one, yet the actual phenomena would be much more complex. The main novelty, however, was Sir George Stokes's suggestion. In assuming some time ago that if Sir George abandoned a "periodic" hypothesis he had nothing left but a corpuscular one, the possibility that his theory might be one of solitary waves did not occur to us, since it did not seem clear how such waves, if of the same magnitude, would behave very differently from ordinary light waves. The theory of single waves is by no means so well known as that of the indefinite succession of similar undulations. What would happen of course depends on what assumptions are made as to the intimate structure of the medium, but it seems clear that if the change from one medium to another were sharp enough, such single waves would be reflected in the usual way. Moreover, although we have got into the habit of considering, for simplicity, a beam of ordinary unpolarised light to consist of an indefinite succession of similar vibrations, it is obvious that it cannot be so in fact, and the uniformity is only "statistical," and due to the circumstance that the smallest portions of space and time we can deal with are large in proportion to the dimensions of the waves. There should be contained in such light at least some series of a comparatively small number of similar waves. It is therefore still necessary to assume that the solitary waves are much shorter than the ordinary light wave, and it does not seem at present to matter much whether, when the average is taken, they are assumed to be solitary or "successive." There are, however, electrical reasons for thinking it probable that the number of vibrations of the originating source is in each case small. As to longitudinal waves, unless the writer has made a mistake—not a difficult thing to do in these matters—the mathematical difficulties in the way of the transmission of any serious amount of energy by longitudinal ether waves seem insuperable if the suppositions are made which are necessary to prevent results coming out which we know to be untrue. The experiments on the effect of the Röntgen radiations on the conduction of gases are very promising. The effect of a current seemed to indicate that the conduction was electrolytic, and that exposure to the rays formed ions in the gas. But the filtration experiments seemed to show that the ion of a gas is a large body, larger than an air molecule. This is, of course, quite contrary to what is usually supposed to be the case with the ions in a liquid electrolyte. Further investigation may supply a reason why so many of the physical constants which depend in any way on the theory of a gas come out very nearly, but not quite, what might be expected.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 273.)

Another method of locking the block instruments with the outdoor mechanical signals is shown by Figs. 67-75, which illustrate Sykes's three-wire system, familiarly known as the S.Y.X. system. As in Winter's and Saxby and Farmer's systems, the principal object aimed at is the control of the starting, or advance, signal at the sending end of the section by the signalman at the receiving end, but it is distinguished for the extreme simplicity of the electrical apparatus and for its departure from the usual design of such apparatus.

The system provides a combined locking and indicating instrument for each line of rails, each instrument being provided with a separate line wire; separate bell communication between the ends of each section by which all signals other than those indicating the condition of the line

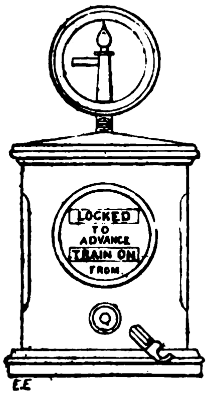

FIG. 67.—Sykes's Block Indicator.

for the time being are sent: a mercury contact rail treadle placed near the starting signal to release the locking arrangements at the proper time; and an automatic signal-arm replacer, fixed on the starting signal, which is also worked in connection with the rail treadle.

The general arrangement of the block indicator is shown by Fig. 67. It consists, as will be seen, of two distinct portions. The upper part containing the small semaphore arm constitutes the block indicator for one line of the *advance* section; whilst the lower part contains the mechanism for interlocking the instrument with the mechanical signal at that place, the electrical apparatus by which the mechanical signal at the *rear* cabin are released for use, and the indicators of the condition of the *rear* section of the same line. One portion of each instrument is, therefore, worked *from* the advance cabin, and the

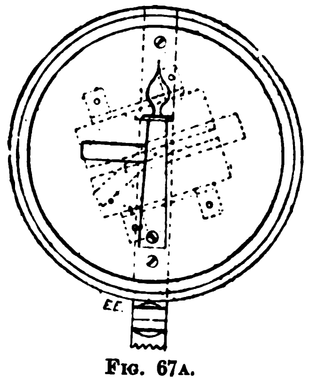

FIG. 67A.

other portion is worked *to* the rear cabin, and the indications of different parts of one and the same instrument give to the signalman information of the condition of both sections so far as one set of rails is concerned.

The construction of the semaphore indicator is shown by Fig. 67A. The position of the arm is horizontal when no current is passing through the coils of the instrument, and in this position the arm indicates the equivalent of "Train on line." When the section is clear of trains on the line of rails represented by the indicator, or of shunting operations at the receiving end of the section, the arm is held in a diagonal position by a permanent current, and indicates in this position the equivalent of "Line blocked." A reference to Fig. 75 will show that the position of the arm is controlled by the signalman at the receiving end of the section, and its indications are in no way dependent upon the actions of the man at the sending end of the section. Fig. 68 is a perspective view of the locking mechanism in

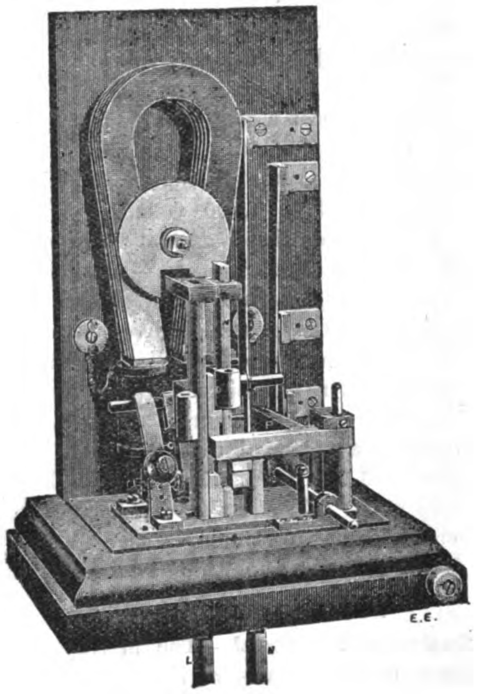

FIG. 68.

the lower part of the instrument. Fig. 70 is a front elevation, and Figs. 69 and 71 are left and right elevations of the same respectively, but the relative positions of the various parts of the apparatus are different in Fig. 71 to the positions the same parts occupy in Figs. 69 and 70. The apparatus consists of a plunger, P, actuated

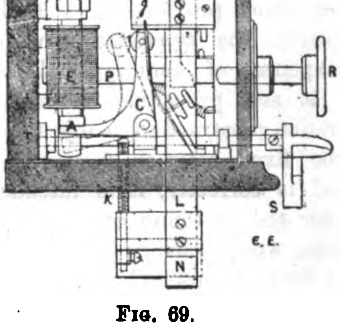

FIG. 69.

by the knob, R, the polarised electromagnet, H, a switch, T, the lock bars, M, *n*, O, and the rods, L and N, in connection with the starting signal mechanism. The plunger, P, at any block cabin makes connection between the spring, S^2, and the battery studs 1 and 2 (Figs. 70 and 75), and sends a current through the polarised electromagnet at the rear cabin in such a direction as tends to weaken the attraction of the permanent magnet upon the soft-iron armature. The armature, A (Fig. 69), is carried by one arm of a bell crank, C, the vertical arm of which

Digitized by Google

carries a small friction wheel. A pin projecting from the vertical arm causes the latter to be acted upon by the strong spring, F (Fig. 70), which tends to separate the armature from the poles of the electromagnet. Under normal conditions A is held by the attraction of the polarised electromagnet, and the release is effected by passing a current of such strength and direction as will allow the spring, F, to overcome the diminished attraction of

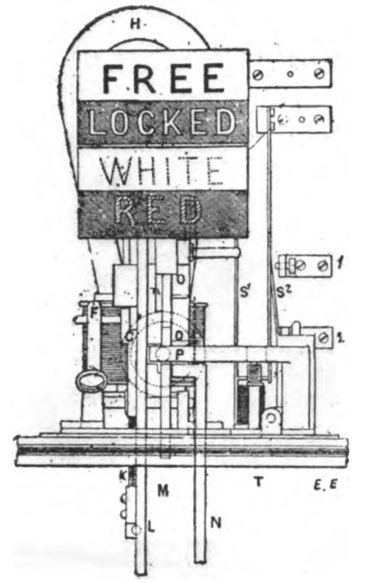

FIG. 70.

H. The switch, T, is used in connection with the one-cell battery shown in Fig. 75. This battery is used simply to hold the semaphore indicator at the rear cabin in the "off" position when the section is clear of trains on the line of rails it represents, and no operations involving the fouling of this line are being carried out. The lever, L, is pivoted at *c* (Fig. 72), and carries at one end of the arm the lock rod, *d*, for the signal lever, and at the other end the friction wheel, *b*. The continuation of L within the case of the instrument carries a light frame, on

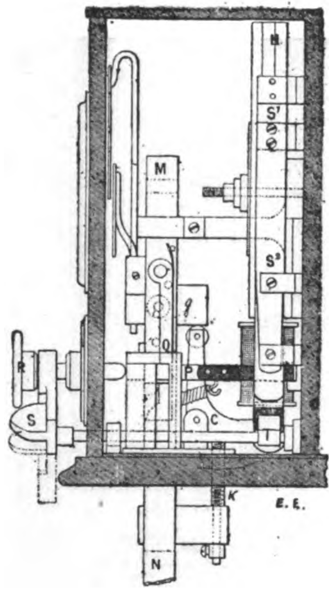

FIG. 71.

which is painted "free," "locked" (Fig. 70). These indications appear, in their proper order, at the upper opening of the instrument case, and indicate to the signalman the condition of the starting or other signal connected with L. Within the case L carries the projection, *g* (Figs. 69 and 71), which rests upon the friction wheel of C, as shown by the full lines in Fig. 69. Under the instrument L carries the parallel bolt, *k*, which, passing into the interior of the instrument, engages with the horizontal arm of C and raises the armature, A, into contact with H, when the motion imparted to L by the movement of the signal lever is upward. When the projection, *g*, rests upon the friction wheel of C the weight of L is supported by the latter, and the short arm pivoted at *c* (Fig. 72) is in such a position as to lock the signal lever in the "on" position. If the armature, A, is released L is lowered until the friction wheel, *b* (Fig. 72), rests upon the semi-circular rim of the double bell crank, and by doing so lifts the lock rod, *d*, into the position shown by Fig. 72 and releases the lever. At the same time the word "locked" disappears, and "free" takes its place at the upper opening of the instrument, indicating to the signalman that the lever is free to be placed in the "off" position. The tongue, *t* (Fig. 72), working on the same centre as the double bell crank, is loose, and works in a V groove on the vertical face of the crank. When the lever is placed in the "off" position *t* passes under the friction wheel, *b*, and raises L, and, in consequence, the armature, A, is raised into contact with the poles of H by *k* and held there. The word "free" disappears and "locked" takes its place at the upper opening of the instrument, indicating, in conjunction with the position of the signal lever, that the latter is locked in the "off" position. Consideration of Fig. 72 will show that this is really the case, and the signal lever cannot be fully replaced in the "on" position until the armature, A, has again been released. This release takes place when the train passes over the rail treadle near the signal actuated, and the word "free" again replaces "locked" at the opening in the instrument case. In replacing the lever in the "on" position, *t* again raises L and the armature. The latter is retained by H, and the former

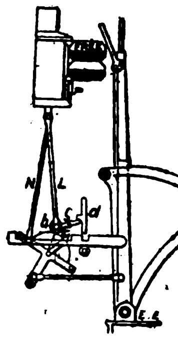

FIG. 72

by projection, *g*, resting on the friction wheel of C, and, so far as the electrical control of the signal is concerned, the apparatus is ready for a similar cycle of operations. The word "locked" again appearing at the opening indicates the locking of the signal lever in the "on" position. The slotted lock bar, M, carries on one side the swinging lever, O (Figs. 69, 70, and 71), and on the other side a second slotted bar, *n* (Fig. 70). As seen in Figs. 69 and 70, O is resting on the top of the rod, N, which is in the position it occupies when the signal lever is in the "on" position. If the plunger, P, is depressed under these conditions, the lever, O, is pressed back until it clears N, and the lock bars, M, *n*, O, drop into the position shown by Figs. 68 and 71 when the plunger is released. The mechanical result of this operation is to exhibit "Train on" at the lower opening of the instrument, and to place the slots of the lock bars, M *n*, in such positions, relatively to the plunger, that the latter cannot be again depressed until certain operations have been performed. The electrical results following the depression of the plunger are the breaking of the one-cell battery circuit by the fall of M (up-line instrument at "C," Fig. 75), and the consequent raising of the semaphore arm at the rear cabin to the horizontal position (up-line instrument at "B," Fig. 75), and the unlocking of the armature, A, at the rear cabin, by the current established by the contact of the spring, S^2, with the battery studs 1 and 2 (Fig. 75). A glance at Fig. 72 will show that when the signal lever is pulled into the "off" position, the rod, N, is drawn downward, and if the plunger has been previously depressed N will slide over the sloping face of O (Fig. 71), pressing it back meanwhile, until it reaches its lowest point, when O being free of N, again takes up a position imme

Digitized by Google

diately over the latter. In replacing the signal lever in the "on" position, the upward movement of N raises M, *n*, and O into the positions shown in Figs. 69 and 70, when the plunger is available for use again. If it should be required to place the signal lever in the "off" position, without previous use of the plunger, as would be the case for a train issuing from a relief siding, such as is shown by Fig. 10, the lowering of N simply lowers M, *n*, and O into the position previously described, when, as before, the signalman is unable to depress the plunger in order to allow a train to leave the rear end of the section. It is evident therefore that a necessary condition of the use of the plunger is that the signal lever controlling entrance to the advance section shall be in the "on" position.

(To be continued.)

ELECTRIC GLOW LAMP TESTS.*

BY WILLIAM HENRY PREECE, C.B., F.R.S., ETC.

(Concluded from page 382.)

It will be seen that the only group which started at about its stated candle-power was Group G, of 3 to 4 watts per candle. This began with a mean candle-power of 15·56, and at the end of 1,000 hours' lighting reached an approximately constant candle-power of 12·5 per lamp. The watts per candle started at 3·57 per lamp and finally attained 4·7.

Group H, that of over 4 watts per candle, commenced with a candle-power of 13·43, and fell to about 10·5 in 1,000 hours, while the watts per candle varied from 4·5 to 5·6 per lamp.

Group F comprises high-efficiency lamps, and comes out somewhat unsatisfactorily, as the starting candle-power of the lamps is only 12·57. It should, however, be remembered that it consisted of three lamps only, hence a good mean result could not be obtained. During the 1,000 hours the candle-power fluctuated considerably, owing to new lamps taking the place of old ones, and at the end of this time it dropped to 7·82 per lamp, while the watts per candle throughout the time changed from 2·72 to 4·84. It will be seen in this case that at the end of 1,000 hours the so-called high-efficiency lamps required more watts per candle than those of Group G.

Sheet 3 graphically represents the lamps replaced in each group, expressed as a percentage at intervals of 100 hours taken from the following figures.

TABLE 7.—Percentage Number of Lamps Replaced.

Time. Hours.	Group H.	Group G.	Group F.	Remarks.
0	—	—	—	—
100	0	5·3	0	—
200	0	5·3	33·3	—
300	0	10·5	33·3	—
400	0	26·3	33·3	—
500	0	26·3	66·7	—
600	0	36·8	100·0	—
700	0	36·8	100 0	—
800	0	42·1	100·0	—
900	7·1	47·4	133·3	—
1,000	14·3	63·2	133·3	—

Group F = 3 lamps of initial efficiency = 2·3 watts per candle.
,, G = 19 ,, ,, ,, = 3·4 ,, ,, ,,
,, H = 14 ,, ,, ,, over 4 ,, ,, ,,

If the number of lamps in either group was sufficiently large, the curves on Sheet 3 after a time would become straight lines at different inclinations to the axis of time. The tangent of this angle denotes the rate of replacing the lamps with time. One hundred divided by this, when the constants for percentage of lamps and time are suitably taken, would therefore give the mean life of the lamps, since, at that time, all the lamps would have been replaced.

Thus in Fig. 2 :

$$\frac{y}{x_1} = \tan\theta, \text{ or } x_1 = \frac{y}{\tan\theta}.$$

$$\therefore \text{ Mean life of lamps} = \frac{100}{\tan\theta}.$$

Owing to the small number of lamps in each group the curves are not continuous, but it will be seen from Curve F in Sheet 3 that all the high-efficiency lamps are replaced in about 700 hours ; in the case of Curve G all the three to four watt lamps would be replaced in about 1,350 hours, and in the case of the low-efficiency lamps in Curve H there were only two failures out of 14 lamps after about 1,000 hours. It is therefore impossible to approximate the mean life of the lamps plotted in Curve H, but it can certainly be taken at considerably over 1,000 hours.

From Sheet 2 it will be manifest that the lamps of from three to four watts per candle give the greatest candle-power per lamp—from 700 to 1,000 hours—with the least expenditure of energy per candle. To see which type of lamp was the most economical to use, the curves on Sheet H, connecting cost per candle-hour and time were calculated, as in the following Tables 8, 9, and 10, at intervals of 100 hours from the formula:

$$\text{Cost per candle-hour} = \frac{\text{The price of total number of lamps used.}}{\text{Total candle-hours up to that point.}} + \frac{\text{Mean watts per candle up to that point}}{1{,}000} \times \text{price of B.T.U.}$$

In the following Tables 8, 9, and 10, the cost per lamp has been taken at 1s. 3d. throughout.

In the instances taken an inspection of these curves show that even when the price per Board of Trade unit is as low as 3d. at the end of 1,000 hours, the high-efficiency lamp has to give way to those of Group G. The same remark holds in a less degree when the price of a Board of Trade unit was taken at 6d., but when the price of energy is raised to 9d. per unit the lamps occupy the relative positions indicated by their initial efficiencies, though there is not much difference between Curves G3 and F3. In this comparison, however, it must be borne in mind that the candle-power of the high-efficiency lamps was considerably under the normal at the start, and it is reasonable to expect that if the lamps as per Group F could be obtained, giving a mean candle-power of 16 at the start, they would be found to be more economical even when the price per unit is as low as

CURVES SHOWING PERCENTAGE OF LAMPS REPLACED.—Sheet 3.

As compared with Prof. Ayrton's and Mr. Medley's excellent paper, I think the foregoing results based upon the greater number of lamps, lamps of different makers, and lamps of different efficiencies, furnish a more satisfactory idea of the cost per candle-hour, and also of the most economical lamp to employ. As regards high-efficiency lamps, if they could be relied upon to start at their marked candle-power, they would certainly be found of good service for domestic lighting and for large open spaces where a considerable reduction of candle-power of individual lamps would not cause inconvenience; but in large establishments like the Post Office, where each lamp must give a fairly uniform light over a long period, they could not be tolerated.

Cost per candle-hour in pence.

CURVES CONNECTING COST PER CANDLE-HOUR AND TIME.—Sheet 4.

A copy of the present Post Office specification for glow lamps is given below. It is not yet regarded by me as being in its final form, but so far the conditions laid down have been satisfactorily met by certain lamp-makers, and this has resulted in a considerable improvement in the lamps supplied. We frequently find that weakness is apparent at the lamp mounts through the wires being too thin, and the joints between the metal and filament being defective.

Test No. 2, in conjunction with 1 and 3, has proved to be a valuable means of finding out the good, bad, and indifferent qualities of lamps; it is found to give a good forecast of what a lamp would do when used in the ordinary way, and may be regarded as equivalent to so many hundred hours' run. I also attach results recently obtained with some new two-watt lamps. The drop in candle-power with these lamps, as with all other economical lamps that I have tested, is very large during the first two to three hundred hours' run, after which time they seem to reach a steady state and behave like ordinary three to four watt lamps, but at this stage the illuminating power is no longer serviceable for post and telegraph work, hence the lamps would have to be frequently renewed.

These experiments have been tedious and exhaustive. They have been carried out under the indefatigable supervision of Mr. Isaac Probert.

* Lamp considered useless, so test discontinued.

POST OFFICE TELEGRAPHS.—ELECTRIC GLOW LAMPS.

SPECIFICATION referred to in the accompanying form of tender.

Size of Lamp and Terminal.—The glow lamps are to be to the size of a sample which is to be submitted for approval with the tender. In the case of lamps with screw holders, the screw terminal is to be strictly in accordance with a standard which will be supplied to the contractor, and to be of such a size that it can be screwed home in the Post Office standard gauge and accurately fitted.

Marking.—Each lamp is to have distinctly marked on the glass the voltage, the candle-power for which it is designed, and the maker's name, with the normal watts per candle-power.

Examination and Rejection of Broken or Defective Lamps.—Each lamp will on receipt be tested for continuity of circuit. All lamps having broken filaments, loose terminals, or which are otherwise of defective manufacture, will be rejected, and an equivalent number of good, sound lamps must be supplied free of charge by the contractors.

Lamps to be Selected for Test.—From the bulk of each delivery a number of lamps will be selected at random and tested electrically and photometrically. This number will vary according to the quantity delivered—viz., 3 per cent. of a delivery of 1,000 lamps or under, 2 per cent. of a delivery of 1,000 lamps and up to 3,000, and 1 per cent. of a delivery of over 3,000 lamps, will be tested. The Postmaster-General reserves the right to reject the whole delivery if more than 25 per cent. of the total number so selected fail to pass either or all the tests hereafter specified. If further tests are undertaken at the contractor's request, it will be at his risk and cost.

Tests.—The following tests will be applied to all the selected lamps: (1) A photometric test to determine the actual candle-power of the new lamp at its standard pressure, and an efficiency test to determine the watts per candle. The limits of candle-power and the maximum watts per candle-power allowable for each kind of lamp tendered are set out in the attached table. (2) After being so tested, the pressure at the lamp terminal will be gradually raised until it reaches in $2\frac{1}{2}$ minutes the pressure stated in Column 5 of the table. This pressure reached, the current will be at once turned off. (3) The lamps will then be retested, as described in test No. 1. The limits allowable for each kind of lamp as regards candle-power, and the maximum watts per candle-power, are set forth in the attached table. (4) In lieu of Tests 2 and 3 a proportion of the lamps not exceeding one-third of the whole number selected for test will be raised gradually in three minutes to the pressure stated in Column 7 of the table. The lamp under test must not fail in any way while the pressure is being increased from its normal voltage to that named in Column 7 of the table. (5) The candle-power of all lamps tendered for must be in terms of the English standard candle.

NOTE.—The Post Office measurements will be made with an improved Trotter photometer, and the standard of light will be either the Vernon Harcourt or the Hefner amyl-acetate, the former being taken for the purposes of this specification as one English candle, and the latter as ·88 of an English candle.

Signature of person tendering..........................

General Post Office. Date.......................

DISCUSSION.

Mr. H. Graham Harris asked what difference there would be in the lamps if alternating current were employed and how the specification would be altered to meet those conditions.

Prof. Ayrton said there was no question of the value of the investigations carried out by Mr. Preece. One of the things they wanted to know was the behaviour and life of the cheaper form of lamps which had been brought into this country, therefore the life tests were not only of importance to Mr. Preece and Post Office, but to all who were interested in electric lighting by means of glow lamps. He should like to hear how many lamps were used in obtaining the results given. For example, under Table Group A, it was stated that two lamps out of 24 of each make were selected at random, one 16 c.p. and one 8 c.p. Did that mean that tests were made on two lamps only, or were the results obtained from a large number? Tests in his (Prof. Ayrton's) laboratory had shown that unless a large number of lamps of a particular type were tried no results of any great value could be derived because of exceptional lamps of any particular make being extra good or bad. With reference to the breakage tests and running up the pressure to nearly twice, he thought if the results were borne out they were of very great importance. The least value that Mr. Preece had arrived at under the most favourable conditions was ·015d.; it ought to be borne in mind that even that most favourable result was a good deal higher, not lower, than lighting by gas with ordinary Argand burners, and was far dearer than gas with the Welsbach lamp. He had been recently carrying out life tests on a lamp which was not before the public, the filament of which was carbide of silicon. The speaker spoke eulogistically of this lamp, and added that after 1,000 hours the consumption was not higher than 3·75 watts per candle. He had been occupied in considering whether the candle-power rise was due to increase of vacuum, and had found by means of an induction coil that lamps in which the light improved was due to an improvement in the vacuum. Generally speaking, lamps in which the candle-power rose were incomplete; they were sold as complete lamps, but the filament gradually changed until the lamp was very much improved.

Prof. Fleming expressed surprise that Mr. Preece had adopted as his standard of comparison the standard candle on the Rumford method of shadow photometry. He, the speaker, had abandoned all forms of standard candle many years ago. The standard candle-power in the Act of Parliament and in the spermaceti were quite different matters. Photometry was not a question of instrument: it was one of observer, and for that reason he objected to all comparisons taken through red and green glass. What they wished to get at was the brightness upon a white surface as compared with the surface produced by a standard source of light. The Hefner lamp had been used a good deal in Germany, but was too red a standard, in addition to which there were difficulties in using it on account of ventilation. The Vernon Harcourt was a standard of very great value, and many observers had given it the first place. Mr. Preece had not referred to the standard, which was a modified platinum standard first suggested by Violle. In using an incandescent lamp as a secondary standard, there was a difficulty in measuring the rate of decay. He (the speaker) had adopted a method of using 16-c.p. filaments in large bulbs, and such secondary standards were exceedingly valuable. He should like to see in the first paragraph of the specification a more definite method suggested of placing the filament with respect to the photometer. Very little alteration in the filament would mean a variation of candle-power. He should like to see a final definition of the standard candle. At the present moment it was not sufficiently well defined. After referring to other clauses he suggested that the specification should be further discussed before final adoption, otherwise it might deal very differently with different classes of lamps.

Mr. Swan thought that the short test described in the paper was by no means a bad one, and very valuable information was derived from it. If the voltage was raised gradually during $2\frac{1}{2}$ minutes to 170 volts, and if the lamp did not break, he thought it strong evidence that the lamp is representative of a class, supposing it to be taken from a group of lamps.

Major-General Webber said in spite of the long monopoly and that the number of manufacturers had trebled since 1884, no one appeared to have thought it worth while to prepare a specification on behalf of the consumers. He thought that the specification would be an admirable document if minor alterations were made. Lamp manufacturers, however, he thought, had used all the

Digitized by Google

methods of testing suggested by Mr. Preece. With regard to the specification, he remarked that if Mr. Preece could urge the makers to mark on the lamps, along with the other figures, the normal watts per candle, it would be of great use.

Mr. Preece, in replying, said it had been pointed out by Mr. Robertson that the alternating current had no different effect on the glow lamps. Prof. Ayrton had pointed out that though the cost of electricity was infinitely small, it was still greater than that of gas. Gas per hour was unquestionably cheaper than electric light; the economy of the electric light was not during the time it was burning, but one only used it when it was wanted. A gas burner was used twice as long as an electrical one. He suggested that if the Liverpool Corporation worked their trams electrically they could sell electricity at 3d. per unit. He should adopt the recommendations of Prof. Fleming with regard to the specification, and pointed out that new lamps which they had received had indicated upon them the watts per candle.

MEASUREMENT OF ELECTRIC CURRENTS THROUGH AIR AT DIFFERENT DENSITIES DOWN TO ONE FIVE-MILLIONTH OF THE DENSITY OF ORDINARY AIR.*

BY LORD KELVIN, J. T. BOTTOMLEY, AND MAGNUS MACLEAN.

The apparatus used in these experiments consisted of (1) a cylindrical tube 13cm. long and 1½cm. diameter, with two aluminium wires as terminals ground to points 1·5cm. apart; (2) a large Wimshurst electrostatic machine of 24 plates; (3) a high-resistance mirror galvanometer to measure the current between the aluminium point terminals inside the tube; (4) an electrostatic voltmeter to measure the difference of potential between the terminals of the tube; (5) a five-fall Sprengel pump, by means of which the density of the air inside the tube could be reduced to any desired extent. The galvanometer was placed on a block of paraffin between one terminal of the electric machine and one terminal of the glass tube. Its deflections were read by a telescope and its sensibility was arranged by external magnets, so that one division of deflection corresponded to 0·3 mikroampere. Our method of experimenting was to keep the density of the air constant while we varied the difference of potential between the terminals of the tube, and taking simultaneous readings on the voltmeter and on the galvanometer. The electric potential was varied either by varying the speed of rotation of the machine or by varying the distance between the needle-point terminals of the machine, or by a combination of both.

We found that at ordinary atmospheric density it requires a difference of potential of between 2,000 and 3,000 volts at the terminals of the tube before the galvanometer indicates any current. As the difference of potential is now increased, the current through the galvanometer increases at a greater ratio, so that if a curve be drawn with differences of potential as abscissæ and galvanometer readings or currents as ordinates, the curve is always concave towards the axis of current. Through this particular tube the currents at 3,000, 5,000, and 8,000 volts difference of potential were 7·2, 17·6, and 63·2 mikroamperes respectively. As the density of the air was diminished, the difference of potential necessary to start a current, as indicated by the galvanometer, gradually diminished also, till, at a density of about $\frac{1}{1000}$ of the ordinary density, a few score volts were sufficient to start a current. For the same difference of potential the current increased as the density of the air diminished; or otherwise, the same current was obtained by smaller differences of potential as the density of the air was reduced. Thus a current of about 56 mikroamperes was obtained by differences of potential of 7,400, 1,090, 700, 370, 405, 570 volts, when the densities of the air were 1 (ordinary density), 0·058, 0·0093, 0·0007, 0·00006, 0·000024 respectively; or otherwise, when the air pressures were 750, 44, 7, ½, $\frac{1}{22}$, $\frac{1}{55}$ millimetres of mercury respectively.

As the air density was still further reduced, the difference of potential necessary to start a current increased, and the current for the same difference of potential diminished. Thus, when the density of the air was reduced to one five-millionth of the density of air at ordinary atmospheric pressure and temperature, differences of potential of 3,000, 5,000, and 8,000 volts gave currents of 1·3, 4·4, and 14·6 mikroamperes respectively.

If a curve be drawn for a constant difference of potential, with air densities as abscissæ and currents as ordinates, we find the curve rising as the air density is diminished to about $\frac{1}{1000}$ or $\frac{1}{1500}$ of ordinary density; then falling again as the density is still further reduced to about a five-millionth of ordinary density. This is the lowest density we have experimented with, but we have no reason to doubt that at very much lower densities we would still be able to get measurable currents through the tube.

We are now experimenting with a tube 13cm. long and 1½cm. diameter, having ball terminals of ½cm. diameter and about 2mm. apart. The investigation is not complete enough for publishing any results.

REOSTENE: A NEW RESISTANCE METAL.*

BY DR. HARKER AND MR. A. DAVIDSON.

Dr. Harker, of Owens College, Manchester, described some experiments made by Mr. A. Davidson and himself on a new alloy for commercial electrical resistances, which has been called "reostene." This alloy is the outcome of a number of experiments made with a view to find a material of a higher specific resistance than iron, capable of carrying heavy currents, and having only a moderate temperature coefficient. The average specific resistance of the material, as determined from a number of samples, is about 45-46 in terms of copper as unity, and in the specimens examined, which included strip and wire of various diameter down to No. 22 S.W.G., seems to be independent of the size of the wire.

The temperature coefficient of the wire was also determined for a number of samples. For these tests the wire was placed in an apparatus consisting of a cylindrical vessel holding about five litres of an insulated oil, which could be very rapidly stirred by means of a small double screw, placed in a side tube. This acted like a centrifugal pump, removing liquid very rapidly from below, and pouring it back on to the surface. The stirrer was actuated by a small Cuttriss motor placed on an adjustable stand, being coupled to the motor shaft by a piece of stout indiarubber tubing. The liquid could be heated either by means of steam blown through a spiral coil at the bottom of the vessel, or by a current passed through a German-silver wire, wound on a frame immersed in the liquid.

A number of specimens of wire of different diameters were examined in this apparatus, and gave almost exactly the same temperature coefficient ·0011 per ohm per degree Centigrade. This coefficient remains almost absolutely constant within the limits obtainable in this apparatus, 0deg.-60deg. Experiments made with wires in a small furnace at temperatures up to 500deg. C. showed a slight falling off in the coefficient above 100deg. The effect of current on the resistance of the wire was also tested. For this purpose pieces of the wire of 1 or ·1 ohm resistance were fastened by hard solder to copper rings which, by means of screws, could be attached to very stout copper leads and immersed in the bath previously described. Their resistance could be measured at a definite temperature, and they could then be removed, subjected to the treatment desired, and remeasured *at the same temperature under the same conditions.*

For all the resistance measurements a Carey-Foster bridge, designed by one of the authors for platinum thermometry, and recently described in a communication to the Royal Society, was used, and in the opposite arm to the coil was placed a Reichsanstalt manganin standard of negligible temperature coefficient. The resistance measurements were made to an accuracy considerably exceeding anything needed for the purpose of the tests, the last significant figure determined being omitted in the results given.

On treating various specimens of the wire with comparatively large currents only an extremely small variation was found in the permanent resistance. The first effect of the current is slightly to diminish the resistance of the wire, which on longer continued action gradually rose to somewhat above its original value. Selecting at random a specimen case, a coil of No. 14 S.W.G., after a current of 25 amperes had been passed for five minutes, decreased 1 per cent., but after the current had been again passed for four hours, during which time this wire was hot enough to char paper or wood, the resistance had increased to ·09 per cent. above its original value. Similar changes were observed in coils which had been kept for some days in the circuit of a motor, subjected to varying loads.

Only in the case of fine wires which had been heated to a full red heat could any serious change due to current be detected. Oxidation does not occur to any sensible extent below about 250deg. C. The material seems soft, and will stand a considerable amount of twisting force without injury or appreciable permanent alteration in resistance. Its mechanical properties seem only very slightly influenced by the passage of current.

A few tests made on the alteration in resistance of the material when embedded in a fireproof cement and carrying large currents also gave satisfactory results. The wire can be obtained from the makers, Messrs. W. and T. Glover, of Salford.

THE OUTLOOK.

The meeting of the Brush Company, the remarks there made as to the trade of the year, the results of which were given in the balance-sheet, and those relating to prospective work, naturally lead to a closer examination of what has been and what may be. Of indicated work there has been no lack, of actual work there has been a fairly good amount, though all agree that a lull in demand has occurred; but most people think the period of depression to have passed. We doubt if the volume of trade has not all along steadily increased, but the increase was not so large as many sanguine people expected. We believe there are indications of a more rapid increase, but at the same time we are not sure that the work of any individual firm will increase in proportion. Before, however, discussing the reasons for such opinions, another matter referred to at the meetings of all companies may again be brought forward: it is the cut-throat policy followed by nine-tenths of those engaged in the industry. Work has been taken at unremunerative prices, and some of the big firms have been as bad or worse than the smaller ones. The result is well known to all the industry. Again and again has this cheap work turned out badly, and given such trouble that the engineers who have to bear the burden of other people's sins absolutely refuse to hear of, much less sanction, repeat orders when further apparatus is required. There is no reason why these things should not be said: they are "common knowledge" in the trade. The industry, then, has to thank itself for so narrow a margin of profit, and in many directions the margin is even narrower than those who imagine they know really understand. Many pieces of apparatus bear little or no profit for construction—only profit because of patent rights, which enables the factory to charge extra for patented details. A decided pinch will come to some of our manufacturers when these patents run out. We may now briefly state our reasons for thinking that though demand will increase, the business of existing firms may not increase in proportion. The principal reason is simply that more firms are entering the business, and the work will be spread among this greater number. There is now nothing particularly difficult to prevent the average mechanical engineer entering upon the construction of dynamos. The electrical or commercial efficiency to 2 or even to 5 per cent. will not appeal to the buyer. The calculations to be made are nothing compared with those a bridge designer or large roof designer has to contend with, and multitudes are able to make the simple calculations when only a few can make the more difficult ones. Hence our conclusion that with increased demand there will be an increase in the number of firms catering for the demand. Prices cannot be raised, and certainly they cannot be well lowered, for offers are continually being made as, we say, with a very small margin for profit. With regard to central-station work, one phase of the reason for the lull cannot be entered upon just now, but to anyone who carefully considers the history of central-station work and design one cause of the lull will become clear. However, that

Digitized by Google

temporary lull has not been without its advantages, and authorities are beginning to approach the subject with a clearer conception of what they want and of what they must have. Without a doubt the engineers who originally advised the construction of certain central stations did not themselves realise the possibilities of electric lighting. Almost before a year had passed troubles arose from want of room for expansion. Local voters do not want, and will not tolerate, the excessively costly policy of hand-to-mouth construction, and in many places concerns three times as large might have been designed in the first instance. The initial constructional cost of buildings would have hurt nobody, and saved a lot of money and trouble in trying to run over-loaded plants till the extensions were ready. One or two designers in particular have largely adopted the policy of being, as they imagined, on the safe side, and erecting their stations with too little belief in the expansibility of the system. Local authorities who had not so early entered upon the work have seen this mistake, and have waited for a fair indication of what towns really require rather than to make two bites at a cherry. No doubt Mr. Ferranti's views of years ago were at that time as much too wide as some of these we refer to have been too narrow, but even in his case the reality would have been nearer the ideality had there been fewer unforeseen incidents of a disastrous character. As regards the views of many of the local authorities we are in a position to speak at first hand, and we know that more authorities than those whose names have at various times been indicated are seriously considering the question of establishing central stations. Unfortunately, in some cases delay in proceeding has arisen from the seriously conflicting statements of engineers consulted. Promise anything seems to be the established rule in some quarters, providing "I" can get the work. Geese with golden eggs for consulting engineers have been killed by these widely differing promises.

THE ANDREWS RETURN CURRENT CUT-OUT AND SYNCHRONISING SWITCH.

We were recently invited by Mr. L. Andrews to inspect the switching gear he has designed for the Hastings Electric Lighting Company, and the opportunity of seeing the alterations in this historical electric lighting undertaking we gladly accepted. We congratulate the engineer on his success in remodelling the generating plant. In the old days the consumers at Hastings were supplied with incandescent lamps grouped in series on arc lamp circuits. As this necessitated running a group of, say, 10 lamps or none at all, the inflexibility of the system of supply prevented the growth of the undertaking. The present plant in the station is run on the alternating-current system. The engines and alternators were supplied by the Brush Company, and the new supply is rapidly advancing in favour in the town.

After reorganising the arrangements for working the generating plant, Mr. Andrews turned his attention to the switchboard, and has succeeded in his endeavours to overcome several difficulties in alternate-current switching operations. His first idea was to prevent large currents passing when synchronising in case the incoming machine did not fall into step. To this end he designed a switch which would be automatically opened if the alternator began to motor. The switch, which is shown in Fig. 1, consists of two distinct sets of contacts. The first are placed in the porcelain vessels seen in the illustration, and are surrounded by water. The other contacts on the right-hand side are used to make the current only, and the

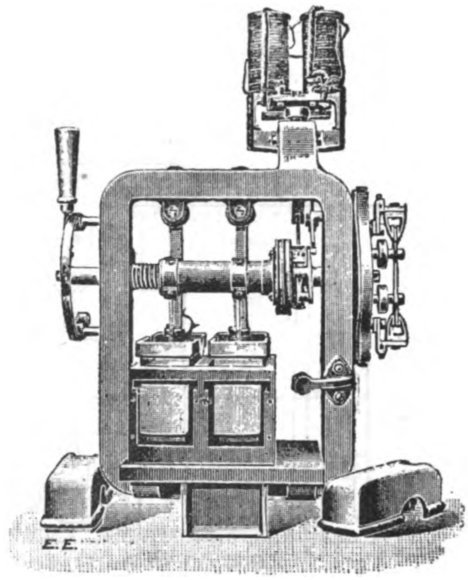

Fig. 1.

circuit is always broken under water. The operation of closing the circuit is as follows: The handle, to commence with, is in the vertical position. As it is pulled forward the right-hand contact is broken, and afterwards the two knives in the water-troughs are brought down into the corresponding jaws. This downward movement of the handle also raises a weight at the back of the switch, which engages with a small trigger under the controlling solenoids. The handle is then brought back

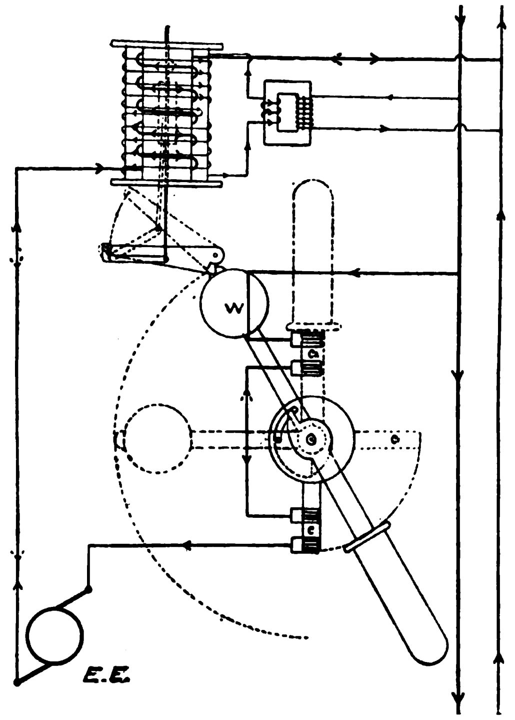

Fig. 2.

into the horizontal position. At this point in the backward motion it is found that the grip of the handle has to be changed. Having again taken hold of the lever, the remaining arc bringing the handle into the original vertical position completes the connection of the machine to the omnibus bars. Before the machine is thrown in the attendant watches the synchronising voltmeter But an error in judgment as to the correct time of throwing in is not serious, as the solenoids will then

Digitized by Google

release the weight, which falling breaks the circuit. In the earlier types of this switch Mr. Andrews used two bobbins with iron cores and an armature. He wound these bobbins with two circuits, one supplied as a shunt to the omnibus bars, and the other in series with the machine. The shunt circuit was, of course, connected on to the secondary of a transformer supplied from the omnibus bars. The connections were so arranged that the magnetising action of the shunt coil opposed that of the main turns when the alternator supplied current to the omnibus bars. Hence, if a current for any reason passed back into the alternator, causing it to act as a motor, the magnetising effect of the two coils was added. The armature then is attracted, and the trigger releases the weight, allowing it to fall and disconnect the machine. The proportional effects of the two coils could, of course, be varied largely, and the switch would again cut out when the current in the main winding rose sufficiently high. The arrangement as above had two objections in Mr. Andrews's opinion. Firstly, if a short-circuit occurred on the mains, these automatic switches would cut the whole supply off before the fuses had time to act. In this way the faulty section would not be localised. The other fault lies in the fact that if the shunt circuits are from any accidental cause broken, the normal current in the main turns would be sufficient to actuate the switch. These two objections have been successfully overcome in the more recent types.

In the two switches seen at the left hand in Fig. 3 a single solenoid is used. The arrangement of the winding on the solenoid is shown diagrammatically in Fig. 2. It will be seen from this that the direction of winding of the shunt coils is reversed in the upper and lower valves. As the core is in its normal position held centrally in the solenoid, the magnetising effect of the shunt winding *per se* is nil. Hence, an accidental interruption of the shunt will not release the trigger. It will also be seen that the direction of the current in the main turns is the same as that in the shunt in the lower half of the solenoid. Thus, when the alternator is supplying current to the mains the core will tend to move downwards. The reversal of the alternator current will, however, produce directly the opposite effect. The shunt and main turns in the lower half will oppose each other, and their joint action in the upper half will lift the core. The actual pull in this case is not nearly so much as could be obtained in the earlier form of the apparatus. In order that this small force should with certainty release the heavy weight required to open the switch, Mr. Andrews has designed a neat compound system of levers, seen in Fig. 2. The action of this catch can be clearly seen from the figure, and it is surprising what a small force is required to release the weight.

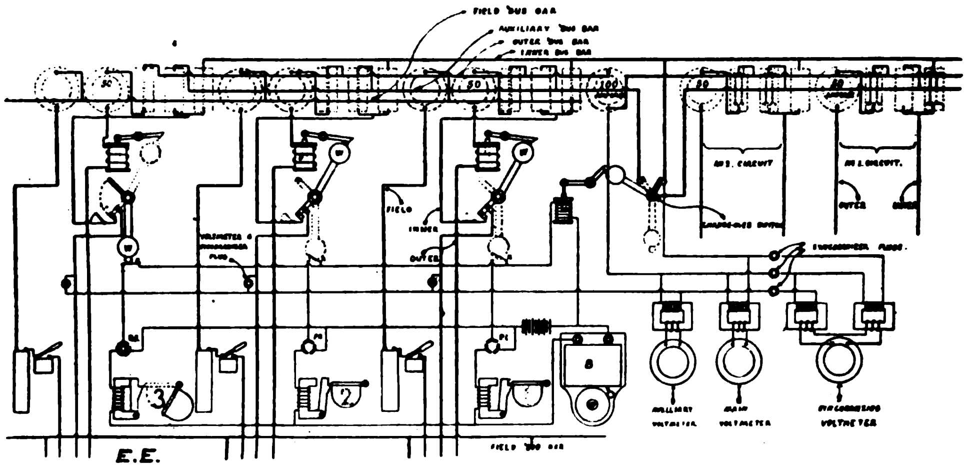

FIG. 3.

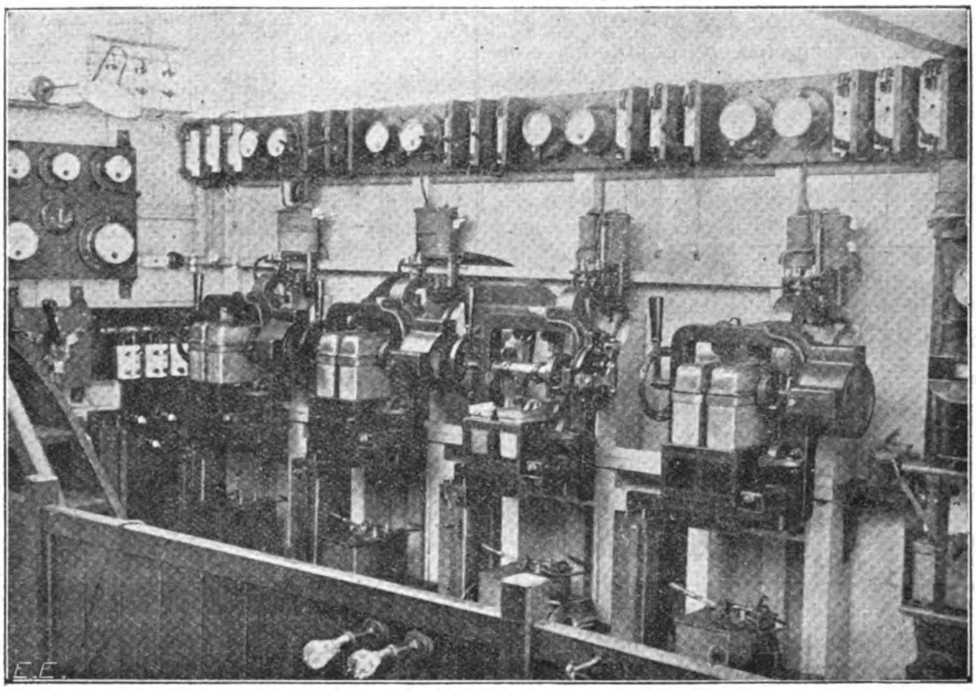

FIG. 4.

We were privileged to see these switches at work last week, and also to try them ourselves. A back current of from 10 to 15 amperes was quite sufficient to release the weight and break the circuit. The switch is, however, so easily reset that if on one forward oscillation of the synchronising voltmeter the alternator does not fall into step when switched in the switch can easily be thrown in again on the next forward swing. In this way repeated attempts to synchronise can be made without upsetting the

Digitized by Google

supply voltage, and also unskilled attendance can be employed. In the switchboard at Hastings single-pole switches have been adopted, but it is only a matter of detail to make the apparatus double-pole. Mr. Andrews has also devised the following means for breaking up the load should a fault occur in one of the machines. Two sets of omnibus bars are provided, and at present two alternators in parallel supply the full load from one omnibus bar. Should, however, one machine develop a fault the load on the other would be excessive. Instead of waiting to parallel a spare plant before throwing out the faulty alternator it is run up on the spare omnibus bars to the correct voltage, and a certain proportion of the load is thrown on to it. This is automatically done by means of a relay actuated by the weight on the switch of the faulty alternator, which closes the relay circuit as it descends. The resultant flicker as the load is transferred from one omnibus bar to the other is hardly perceptible.

The whole connections of the switchboard as now arranged are shown in Figs. 3 and 4. A bell warns the engine attendant when this throw-over mechanism is to be employed, and the indicator also tells him which machine is coming out of parallel. These indicator and bell connections can be seen in the diagram, and give it a complicated appearance. The alternator connections, however, are most simple. In ordinary cases when the load decreases the synchronising switches are always used to break the circuit of the alternator to be shut down. It is then only necessary to regulate the stop-valve of the engine to shift the load on to the other machine, the circuit being immediately broken when the return current passes.

THE DIVISION OF AN ALTERNATING CURRENT IN PARALLEL CIRCUITS WITH MUTUAL INDUCTION.*

BY FREDERICK BEDELL.

A divided circuit with mutual induction between the two branches is shown in Fig. 1, being the same as a transformer with the primary and secondary circuits connected

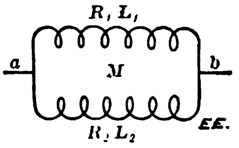

FIG. 1.—Divided Circuit with Mutual Induction.

in parallel. The E.M.F. equations for the two circuits are similar, the internal E.M.F.'s in each being equal to the same impressed E.M.F. The E.M.F. of mutual induction will be positive or negative according to the sense or direction in which the coils are connected. If the coils are connected as in Fig. 2, so that the ampere-turns of the two

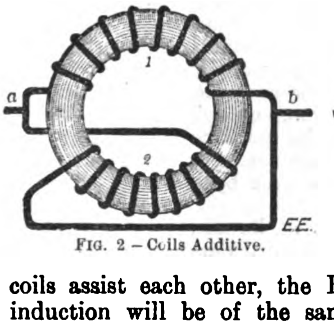

FIG. 2 – Coils Additive.

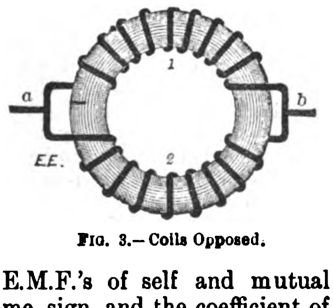

FIG. 3.—Coils Opposed.

coils assist each other, the E.M.F.'s of self and mutual induction will be of the same sign, and the coefficient of mutual induction will be positive. If the coils are connected so as to oppose each other, as in Fig. 3, the E.M.F. of mutual induction will be opposite in sign to that of self-induction. The coefficient of mutual induction may accordingly be + M or − M. Writing the E.M.F. as a function of the time, we have the following equations:

$$e = f(t) = R_1 i_1 + L_1 D i_1 \pm M D i_2 \quad . \; . \quad (1)\dagger$$

$$e = f(t) = R_2 i_2 + L_2 D i_2 \pm M D i_1 . \quad . \quad (2)$$

* Paper read before the British Association at Liverpool.

† D represents the operation $\frac{d}{dt}$.

By differentiation, the above equations become

$$f'(t) = R_1 D i_1 + L_1 D^2 i_1 \pm M D^2 i_2 ;$$

$$f'(t) = R_2 D i_2 + L_2 D^2 i_2 \pm M D^2 i_1 .$$

Eliminating i_2 by determinants, we have:

i_2	$D\, i_2$	$D^2\, i_2$	OTHER TERMS.
0	$\pm$ M	0	$R_1 i_1 + L_1 D i_1 - f(t)$
0	0	$\pm$ M	$R_1 D i_1 + L_1 D^2 i_1 - f'(t)$
R_2	L_2	0	$\pm M D i_1 - f(t)$
0	R_2	L_2	$\pm M D^2 i_1 - f'(t)$

= 0.

Cancelling out the first column and third row, as indicated by fine type, we obtain:

$$M^2 [\pm M D^2 i_1 - f'(t)] \mp M R_2 [R_1 i_1 + L_1 D i_1 - f(t)]$$
$$\mp M L_2 [R_1 D i_1 + L_1 D^2 i_1 - f'(t)] = 0. \quad . \quad (3)$$

From this equation the value for the current i_1 is obtained:

$$i_1 = \frac{R_2 f(t) + (L_2 \mp M) f'(t)}{(L_1 L_2 - M^2) D^2 + (R_1 L_2 + R_2 L_1) D + R_1 R_2} . \quad (4)$$

A similar expression is found for i_2.

For an harmonic E.M.F.

$$e = f(t) = E \sin \omega t ;$$

$$f'(t) = E \omega \cos \omega t .$$

Since $D^2 \sin \omega t = - \omega^2 \sin \omega t$, we may write $- \omega^2$ for D^2.

In equation (4) we may make these substitutions for $f(t)$, $f'(t)$, and D^2. By combining the sine and cosine terms into one term, and multiplying numerator and denominator by D, we have

$$i_1 = \frac{D E \sqrt{R_2^2 + (L_2 \mp M)^2 \omega^2} \sin\left(\omega t + \text{arc} \tan \frac{(L_2 \mp M)\omega}{R_2}\right)}{\alpha D - \omega \beta} \quad (5)$$

where $\alpha = R_1 R_2 - \omega^2 (L_1 L_2 - M^2)$;

$\beta = \omega (R_1 L_2 + R_2 L_1)$.

To free equation (5) from the operator D, perform the operation D as indicated in the numerator (by differentiating the numerator), and multiply numerator and denominator by $\alpha D + \omega \beta$. Substitute $- \omega^2$ for D^2 in the denominator and again perform the operation D in the numerator. We thus obtain an expression for i_1 which is free from D; this may be written in the following form:

$$i_1 = I_1 \sin (\omega t + \phi_1) . \quad . \quad . \quad . \quad . \quad (6)$$

where

$$I_1 = \frac{E}{\dfrac{\sqrt{\alpha^2 + \beta^2}}{\sqrt{R_2^2 + (L_2 \mp M)^2 \omega^2}}} . \quad . \quad . \quad . \quad (7)$$

$$\phi_1 = - \text{arc} \tan \frac{\beta}{\alpha} + \text{arc} \tan \frac{(L_2 \mp M)\omega}{R_2} \quad (8)$$

Similarly, for the current in the second branch,

$$i_2 = I_2 \sin (\omega t + \phi_2) \quad . \quad . \quad . \quad . \quad (9)$$

where

$$I_2 = \frac{E}{\dfrac{\sqrt{\alpha^2 + \beta^2}}{\sqrt{R_1^2 + (L_1 \mp M)^2 \omega^2}}} . \quad . \quad . \quad (10)$$

$$\phi_2 = - \text{arc} \tan \frac{\beta}{\alpha} + \text{arc} \tan \frac{(L_1 \mp M)\omega}{R_1} . \quad . \quad (11)$$

The ratio of the two currents is

$$\frac{I_1}{I_2} = \frac{\sqrt{R_2^2 + (L_2 \mp M)^2 \omega^2}}{\sqrt{R_1^2 + (L_1 \mp M)^2 \omega^2}} . \quad . \quad . \quad (12)$$

Their phase difference is

$$\phi_1 - \phi_2 = \text{arc} \tan \frac{(L_2 \mp M)\omega}{R_2} - \text{arc} \tan \frac{(L_1 \mp M)\omega}{R_1} . \quad (13)$$

Where the coils are opposed and nearly similar, the angle of phase difference between the currents depends largely upon the amount of magnetic leakage.

The diagram for the E.M.F.'s in a divided circuit in which the effects of self and mutual induction are additive is shown in Fig. 4. The two currents are I_1 and I_2 respectively, the main current being their vector sum I. In branch one O H is the power E.M.F. (in the absence of branch two); H J and J K are the E.M.F.'s of

Digitized by Google

self and mutual induction, being at right angles to the currents I_1 and I_2 respectively. The corresponding E.M.F.'s for the second circuit are shown in the same diagram. The sum of the several E.M.F.'s in either circuit add up to E, the impressed E.M.F. Ordinarily, the branch current and the main current would lag behind the impressed E.M.F. by a large angle approaching 90deg. When the two circuits are identical, the branch currents, I_1 and I_2, would have the same magnitude and direction; the points H' and J' would coincide with the points H and J respectively. An inspection of the figure will

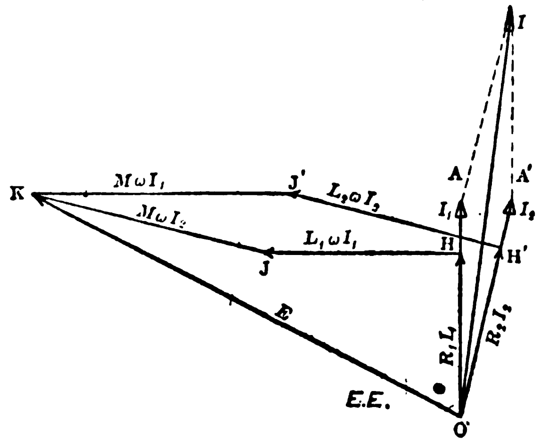

Fig. 4.—Coils Additive; *M* Positive.

show that for this case, in the absence of magnetic leakage, the effect of the mutual induction would be to double the tangent of the angle of lag. Fig. 5 shows the corresponding diagram for the case in which the E.M.F.'s of self and mutual induction are opposed. The current I_1 produces an E.M.F. H J in the first branch and J' K in the second branch, these E.M.F.'s being at right angles to the current, I_1, and opposite to each other in direction, on account of the sense in which the two coils are connected. Similarly, H' J' is opposite in direction to J K. The effects of self and mutual induction consequently tend to neutralise each other. The E.M.F. O K, required to cause the currents I_1 and I_2 to flow, is accordingly made less on account of the mutual induction, and would be reduced to the value of the ohmic E.M.F. in the case of two similar coils wound

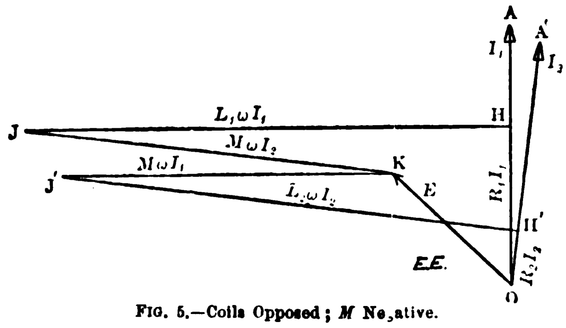

Fig. 5.—Coils Opposed; *M* Negative.

oppositely. In this case the angle of lag would be reduced to zero and the coil would be non-inductive. The equivalent resistance and self-induction for the two coils together, whether they are additive or opposed, may be found by resolving E into two components, one in the direction of the main current and the other at right angles to it. These components will be equal to R' I and L' ω I respectively. Their magnitudes may be obtained graphically, and from them the values of the equivalent resistance, R', and the equivalent self-induction, L'. The equivalent resistance and self-induction of either branch may be obtained in the same manner.

The conclusions relating to the special case of two identical coils wound without magnetic leakage, stated above in connection with the graphical construction, may be reached by substituting in the formulæ the values $R_1 = R_2 = R$; and $L_1 = L_2 = \pm M = L$. Also, $\beta \div \alpha = 2 L \omega \div R$. The two cases are as follows:

When M is Positive.—When M is positive, the coils being wound in the same direction,

$$\phi = -\text{arc tan}\frac{2 L \omega}{R} + \text{arc tan } 0 = -\text{arc tan}\frac{2 L \omega}{R}. \quad (14)$$

The current in each branch is

$$I_1 = I_2 = \frac{E}{\sqrt{R^2 + (2 L \omega)^2}} \quad . \quad . \quad . \quad (15)$$

For this case, therefore, the effect produced is the same as though the mutual induction were zero and the self-induction of each circuit doubled, the tangent of the angle of lag being doubled and each current being diminished accordingly.

The main current is

$$I = I_1 + I_2 = \frac{2 E}{\sqrt{R^2 + (2 L \omega)^2}} = \frac{E}{\sqrt{\left(\frac{R}{2}\right)^2 + L^2 \omega^2}} \quad (16)$$

which is the same that would flow in a single coil with the same self-induction and half the resistance as either branch.

When M is Negative.—When the coils are identical and opposed,

$$\phi = -\text{arc tan}\frac{2 L \omega}{R} + \text{arc tan}\frac{2 L \omega}{R} = 0; \quad (17)$$

$$I_1 = I_2 = \frac{E}{R}. \quad . \quad . \quad . \quad . \quad . \quad (18)$$

Each coil acts in this case as though non-inductive, the magnitude of the current being in accordance with Ohm's law, and the angle of lag being zero.

Cases where the two coils are not identical may be treated by substituting particular values for the resistance and coefficients of induction in the general equations.

APPLIED ELECTRO-CHEMISTRY.*

BY JAMES SWINBURNE.

LECTURE III.

Removing Tin from Scrap.

As sheet tin has from 3 to 5 per cent. of pure tin, it is clear that if all the scrap could be collected and have its tin taken off, the process would be very valuable. Tin is a very expensive metal, worth, say, £80 a ton. If scrap tin is worth £1 a ton, £100 worth would contain £240 worth of tin, and the iron or steel would be worth considerably over £100. The presence of tin makes scrap tin useless as iron, but if it is completely removed the scrap can be worked up into good quality iron. My attention was specially attracted to tin by an inventor who came to me with a patent for stripping it. As the patent he owned seemed useless I worked out another process. This was not electric, and consisted in dipping the scrap in baskets into fused caustic. If old tins were used this also melted out the solder, and corroded labels and varnishes so as to get at and remove the tin under them. The resulting stannate of soda was to be sold in that state, as it is a marketable chemical. The scrap coming out of the fused caustic had a good deal of the caustic sticking to it. It would, on a large scale, therefore be washed in successive baths, getting weaker and weaker, and ending in water; the liquid being gradually moved up into the fused vat to replace that removed as stannate. By this means the expense of evaporating down all the caustic that adhered to the tin could be kept down. This process works fairly well, but it is difficult to get the caustic to take up enough tin. The stannate thickens it very quickly, and the resulting mixture never contained enough stannate to be a commercial article. The tin could be easily removed from the caustic by electrolysis, and came down well.

This process seemed fairly promising, but at this stage it was found it had been tried before. A company had been formed to work it. Whether that company is now flourishing or not I do not know. As a matter of fact the process is probably quite old, as it is fairly obvious, and the skinning of scrap tin has exercised a great fascination for inventors for years.

As it was of no use going on with an old process, another method was sought. Acid electrolytes attack the iron as well as the tin, and were therefore out of the question. Curiously enough, if sheet tin is used as anode in caustic soda solution, the tin does not go into solution; oxygen comes off. I had tried a number of experiments in 1882 with sheet tin as backing for peroxide plates in alkaline solutions for secondary batteries. If sheet tin is boiled in caustic lye the tin is not attacked. If clean iron is dropped in, bubbles of hydrogen come off the iron, and tin goes into solution. Strangely enough, however, this process does not act, because very soon the clean iron gets coated with tin, and

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

the action stops. It is very odd that tin should be eaten off one piece of iron and then deposited from the solution on to another piece. This gave the key to the electrolytic process. All that is needed is to heat the caustic bath. The anode no longer gives off oxygen, and the tin is stripped off perfectly and deposited nicely on the cathode.

This process seemed perfectly successful; the next thing was to try it commercially. There are supposed to be thousands of tons of scrap tin wasted every year. It is said to be largely used for mending roads. When we tried to get it none was forthcoming; and it seems as if the whole idea of there being an important industry in the recovery of tin from scrap is erroneous; the difficulty is to get the scrap. Makers of large tin goods sell their clippings to people who do smaller work, and, finally, the scrap is distributed in such a way that it cannot be collected profitably. The recovery of tin and lead from old cans might be carried on on a very small scale by corporations, but it is questionable if it would pay, owing to the quantities available. This is an illustration of the principle that the great difficulty of the inventor is to discover a long-felt want.

Aluminium.

It would be of little use, even if there were room for it, to write a long description of the manufacture of aluminium by the various electrical processes, as full accounts of the works at Niagara, and to some extent of the Swiss and French, as well as the English works, have frequently gone the round of the technical journals.

It is very difficult to know what place aluminium will ultimately take in commerce. It is first to be a marvellously strong, light, and cheap metal, practically indestructible, and combining all the good points of all other metals; then it is run down as being soft, treacherous, easily corroded, and only useful in a few overrated alloys. The truth, of course, lies between these extremes. It is now becoming more generally realised that aluminium has really a very great affinity for oxygen, even at ordinary temperatures. The only reason why it does not combine with the oxygen of the air quickly enough to catch fire seems to be that the coating of oxide formed is very adherent and hard, and protects the metal. At the same time, it is exceedingly thin, and so transparent that the metal shows a beautiful polish, though the surface is really covered with a crust of alumina. The presence of this thin crust is shown by the difficulty of getting solder to take on to it. The coating of alumina also makes it difficult to make electrical contact with aluminium unless enough force is used to abrade the metal and expose a new surface. I have utilised this property in connection with the telephone used as a galvanometer in a Wheatstone bridge or potentiometer. The telephone circuit is made and broken by scraping a wire over a piece of sheet aluminium. This is far more easily heard than the scraping of a wire over the teeth of a file, or anything of that sort. No doubt the copper wire only occasionally breaks through the coating of alumina, and makes a short contact which is soon absolutely broken by the coating of insulating alumina again. If mercury is placed on aluminium, and the aluminium scraped so as to expose a clean surface to the mercury, the mercury amalgamates it. The amalgam, however, cannot protect itself by an adherent coating of alumina, and the oxide forms in light growths of fluffy alumina. If a drop of fairly strong amalgam of alumina is left exposed to the air, the oxide will grow from the surface of the mercury into a thing like the "Pharaoh's Serpent" which children make by burning sulphocyanate of mercury, when their parents are foolish enough to let them. Caustic alkali, or any acid that dissolves the alumina, will corrode aluminium. Another old experiment which shows the coating of oxide is due to Farmer, who fused a piece of aluminium wire by means of an electric current, and found it kept its form as a perfectly flexible and mobile conductor, which could be deflected by a magnet, and so on. On pricking the wire with a needle the melted aluminium ran out from the inside. This experiment shows that even melted aluminium, which appears beautifully bright and remains clear like silver, is really protected by a surface film of alumina.

The action of dilute acids, such as nitric and sulphuric, is very curious. Though aluminium does not deposit from the nitrate or sulphate in an electrolytic cell, hydrogen coming off instead, it is not at all quickly dissolved in dilute acid. I tried to make use of this property in an electrolytic meter for alternating currents. Two plates were to be employed in dilute acid, the aluminium going into solution at the anode during each half-period, without being deposited at the cathode. No sample of aluminium that I could obtain was acted upon little enough by the acid when there was no current, for such a meter to be accurate within commercial requirements.

Commercial aluminium loses greatly by being impure. Very slight traces of impurity spoil the metal. Commercial aluminium contains traces of silicon, sodium, carbon, and of other metals such as iron. A ½ per cent. or so of sodium is quite a common impurity and may do great harm. It may not be diffused equally throughout the mass, but may be segregated. This not only makes the metal non-homogeneous, and provides veins or flaws of weak metal, but on passing from sodium to aluminium every grade of alloy from nearly pure aluminium to nearly pure sodium is traversed, and some of these alloys are certain to be brittle. Sodium must also have a great tendency to cause corrosion. Not only does sodium oxidise in air and decompose water, but the hydrate formed itself dissolves alumina and attacks aluminium, forming sodium aluminate.

It is questionable if the contamination by sodium can be avoided in the electrolytic processes. There must be sodium present in the electrolyte, and the amount that goes into the metal must be rather a matter of current density and of the strength of the electrolyte in aluminium. Such impurities as carbon and silicon give trouble, not only because they alter the character of the metal, but because they are strongly electronegative to aluminium; and when they are exposed in small particles they form little local couples and give off hydrogen, thus allowing the neighbouring surface to be oxidised. It would probably make a very great difference in the value of aluminium if it could be purified further. Ninety-nine per cent. aluminium is already a commercial product, but it would be worth much more if it were 99·9 or 99·99 per cent. of aluminium. There is a great opening for a cheap and efficacious method of refining this metal further. There are rumours of such a process recently brought out or set to work in Paris, but no particulars are to hand yet.

(*To be continued.*)

COMPANIES' MEETINGS AND REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

The annual general meeting of this Company was held on Monday at the Cannon-street Hotel, E.C., Mr. J. B. Braithwaite, jun. (the chairman of the Company) presiding. Notice had also been given for a special meeting to follow the general meeting in order to consider a reduction in the ordinary share capital of the Company.

The directors' report and the balance-sheet of the Company were published in our last week's issue.

In moving the adoption of the report, the **Chairman** said he was glad to see a large number of shareholders present to listen to the explanation he had to give of the result of the past year's trading. Of course, the results appeared to the shareholders and to the general public to be rather disappointing. To some extent the directors shared that view, but when he had given the explanation he had to make with regard to the circumstances met with during the past year they might be inclined to take a somewhat less pessimistic view of the immediate position and prospects of the Company. To put the thing in a nutshell, the gross trading profit for the past year had been £33,298, showing a reduction of £4,600 as compared with that of the previous year, but this amount, in turn, had been reduced to £2,900 by the economies which had been effected in the expenditure. During the past year they had not received a single large central-station order, and the whole of their profit had had to be made up on comparatively small orders, there having been no large contracts out in the past year. In the previous three or four years they had had a good share of the large contracts then made for the lighting of central stations for municipalities, but it seemed as if other municipalities, though unwilling to let anyone else take the work out of their hands, were waiting to see the result before they themselves embarked any large amount of capital in the electric lighting enterprise. Therefore, in view of the fact that during the past year the Company had not received a single large central-station order, he did not think the result so bad as might possibly have been anticipated, because the whole of the profits for the year had to be made out of orders small in individual amount. In the four previous years they had had an exceptional share of the large contracts for the lighting of central stations for municipalities, and executed orders for the municipalities of Leicester, Worcester, Hanley, and a good many others; but at the present moment there were very few orders of that type in the market. They had, therefore, had to depend entirely on a comparatively speaking retail trade—small orders of £1,000, £2,000, or £3 000—and it took a good many such orders to make up for the dearth of large block orders, and it spoke well for the appreciation in which their manufactures were held that, under the circumstances, the net profits only showed a reduction of £2,900 as compared with the previous year. The second debenture stock which had been issued this year amounted to £76,770. This stock had been made redeemable at the Company's option. Certain large Continental firms had approached them on the subject, and they at length accepted an offer that was made to them to purchase their Vienna business. This had put a large amount of capital into their hands for which they had no immediate employment, and the directors had, therefore, acted wisely last year, when raising this additional capital, to give themselves the opportunity of redeeming it should circumstances render it desirable. Their indebtedness to creditors and on bills payable had been reduced during the year to £33,585, which was less by about £11,300 than the amount shown a year previously. The loan from their bankers had been reduced from £78,097 to £26 775 at June 30 last, and it had since been further reduced to £10,000. It would, he expected, be shortly reduced to a merely nominal sum. The profit and loss account stood this year at £4,615; last year it

Digitized by Google

stood at £7,541. Turning to the other side of the balance-sheet, it would be seen that under the first item they had during the past year been able to arrange what had long been desirable—viz., to get the item of property, patents, and goodwill divided up. Before they had no means of doing so accurately, because when the Company was formed they purchased the undertaking of the Anglo-American Brush Electric Light Corporation and of the Falcon Engine and Car Works for certain payment of shares, which included the whole purchase, and they had no means of dividing the item. To have divided it up in a haphazard way would have been worse than useless. The only possible basis on which they could divide it with anything like certainty was to obtain the services of one of the best-known firms of valuers. They therefore got Messrs. Fuller, Horsey, Sons, and Cassell to make a full and complete valuation. These gentlemen spent two or three months at Loughborough, carefully going through the whole of the works, buildings, and plant and loose tools, and in providing a complete and detailed valuation and inventory of everything the Company possessed there. He did not take any very sanguine view of the value of patents, and had never been a party to paying large sums for them. The only sound method of dealing with patents was to repay the inventor the actual out-of-pocket expenses, and let him depend for his future remuneration upon the results of the sale of his patent articles. If the thing was valuable he got paid. At the same time, it would be a mistake to suppose that the Company owned no good patents. On the contrary, although some of the original patents which the Anglo-American Brush Company bought for large sums in 1876 and 1877 had naturally now run out, yet they had constantly been bringing out and developing new patents, and at present they held in England something like 32 patents of an important character, many of which were bringing in a large volume of orders. In addition, they had a considerable number of foreign patents. Continuing on the subject of the accounts, the Chairman said the difference between what was owing to the Company and what they owed themselves last June represented an amount in favour of the Company of about £85,000. Last June, too, they had in cash £28,714, in addition to the £61,900 then due to them on account of the sale of the Vienna factory. These two sums amounted to £90,614, against £3,910 at the same period a year ago. The shares and debentures held by them in other companies amounted to £61,236 last year, compared with £56,454 this year. Owing to the sale of their Vienna business they had not thought it necessary to publish this year a separate balance-sheet for their foreign branch, and the shareholders were therefore now able to see in one balance-sheet the whole of the assets and liabilities. The valuation which had been made by Messrs. Fuller, Horsey, Sons, and Cassell showed that they had an item for patents and goodwill amounting to £206,000 on which they were expected to earn dividends, but which nevertheless represented nothing directly of a revenue-earning character. Their patents were of great value to them in their business, and the value of their goodwill was also shown by the orders they received; but he did not like to see such an item, however valuable it might be, standing at a large sum in the balance-sheet. The proposal which the directors had made to write off £1 a share on the ordinary shares would enable them materially to reduce the item of patents and goodwill, while it would not diminish by a single penny the amount of dividend which the ordinary shareholders would receive, because whether their shares stood at £2 or £1 they would be still entitled to the whole of the profit earned by the Company after paying the debenture interest and the preference dividend. At the same time, it would, he believed, make the balance-sheet very much sounder. They had felt it wise in connection with this proceeding to extract items under the headings of "stock," "debtors," and "shares and debentures," amounting together to £55,439. None of this amount, however, was known to be actually bad at the present time, or it would have been provided for in the profit and loss account; but, in view of the proposed reduction of the ordinary share capital, they had thought it wise to make provision which would ensure the distribution in subsequent years of the profits they might earn. They intended to keep an ample working cash balance in hand, which was necessary in a company like theirs. Since the financial year closed they had obtained one contract to the value of over £50,000, and such a contract as this required a large amount of working capital to deal with. There was also a considerable demand for the new "Universal" engine which Mr. Raworth, the company's engineer, had invented. Now, however, that the amount due to them on the sale of their Vienna factory had been paid, he thought they would take steps shortly to reduce the amount of the second debenture stock to a round sum of £50,000. He could not forecast what the result of the present year's trading would be, but he might inform them that for the first three months of the current year (to the 30th ult.) the orders they had received were for rather more than double what they were for the corresponding period of the previous year. The outlook, therefore, was very much better, but, of course, it was impossible to say whether it would be equally good for the remaining nine months of the year. With the strong financial position they were now in, and with all their manufacturing facilities, they ought to obtain a very considerable share of the large amount of business which would arise in this country in connection with electrical traction. They were in a position to undertake traction contracts for the entire job, instead of the work being divided among several firms. They hoped great things of electric traction, but it was necessary to exercise a good deal of patience before the matter came into practical working. English people did not rush into things so rapidly as Americans, but now, after a whole year has been spent in negotiations, they had this order of over £50,000, and there were other orders which were likely to come in the present year, so that electric traction would, he hoped, be a source of considerable profit to the shareholders in the near future. Mr. Braithwaite concluded by formally moving the adoption of the report.

Mr. B. H. Van Tromp seconded the resolution, and a considerable amount of discussion followed.

In reply to a **Shareholder**, who enquired whether a director could hold his qualification in preference as well as ordinary shares, the **Chairman** said that the qualification could be held in either class of shares. It would be remembered that the shares were originally £5 ordinary shares, which were divided afterwards into £2 preferred and £3 deferred. The holdings of the directors, however, were largely composed of ordinary shares.

The other **Directors** also stated that they were holders of more ordinary than preference shares.

Mr. Smart criticised the apparent smallness of the gross and net profits during the year.

The **Chairman** said that that he had never pretended that the directors were satisfied with the trading of the past year, and if they thought there was no future for the electrical industry it would be discouraging to go on with such a narrow margin. At the same time, they had done the best they could, and if the shareholders were not satisfied with their efforts they would have an opportunity of electing two new directors in place of those who were retiring. The Company was in a very different position to what it was when he joined the Board; it had now excellent works at Loughborough, with every facility for manufacturing, besides having the large sum of £90,000 at the bankers.

A **Shareholder** asked why they were now proposing to pay back preferential dividend, when it was not cumulative?

The **Chairman** explained that they were now only paying a small sum which had been overpaid to the ordinary shareholders, but which should have been paid on the preference shares. He added, in reply to questions, that the Company held a large stake in the County of London Electric Lighting Company, and the Board expected, if they could hold them long enough, the Company would reap a handsome profit. They also had a considerable holding in the Otis Elevator Company, having an arrangement with that company to manufacture their lifts at the Loughborough works. In reply to a suggestion that the Board should undertake pioneer work, the Chairman said such work had been done in the past, and was responsible for part of the suspense account.

After some further discussion, mostly in reference to the proposal to be made subsequently to reduce the capital, an amendment was proposed and seconded, "That the report and accounts be adopted, with the exception of Clause 9 of the report," but on being put to the meeting was lost, and the original motion adopted, with few dissentients.

A resolution for the payment of the balance of dividend to the preference shareholders having been carried, the retiring directors (Messrs. J. B Braithwaite, jun , and Mr. B. H. Van Tromp) were unanimously re elected, and the auditors (Messrs. Cooper Bros. and Co.) were also reappointed.

The meeting was then made special to consider the following resolution—namely: "That the capital of the Company be reduced from £750,000 divided into 150,000 preference shares of £2 each (of which 90,000 have been issued), and 150,000 ordinary shares of £3 each (of which 90,000 have been issued), to £660,000 divided into 150,000 preference shares of £2 each and 180,000 ordinary shares of £2 each, and that such reduction and alteration be effected by cancelling paid-up capital to the extent of £1 per share on each of the 90,000 ordinary shares which have been issued and by reducing the nominal amount of the said 90,000 ordinary shares from £3 to £2 each, and by subdividing the 60,000 ordinary shares of £3 each, now remaining unissued, into 90,000 ordinary shares of £2 each."

This was moved by the **Chairman**, who said, as to the method proposed, that as the preference and ordinary shares ranked *pari passu* in the case of a liquidation the ordinary shareholders would be in a less favourable position in that event, which, however, they regarded as a problematical and remote possibility, whereas if they had proposed to reduce the ordinary and preference shares *pro ratâ*, which they could have done under the articles of association, an immediate hardship would have been inflicted on the preference shareholders by cutting down their dividend, and there would be a strong opposition.

Mr. A. Sanderson having seconded the resolution, in the discussion which followed a considerable amount of time was occupied in explaining the proposal clearly to some of the shareholders. Some dissatisfaction was shown with the idea of reducing the nominal value of the shares, and the legality of the course taken was questioned. Counsel's opinion (Mr. Palmer) having been read on this point, a suggestion was thrown out that the matter might be deferred for a year. It being explained that one result of this might be that the profits to be earned in the ensuing year might possibly not be available for dividend, a second suggestion was made by **Mr. Fry**, who, with several others, considered that it might be advisable to adopt a different scheme, which would include the preference shareholders. This practically amounted to the appointment of a shareholders' committee to confer with the Board on the subject.

Ultimately, a division was taken on the resolution with a view to adopting this course if the resolution was lost. The directors did not vote, and on counting the body of the meeting it was found that there were 38 for the resolution and 14 against. As a three-fourths majority is requisite for a resolution of this character, this meant that the proposal was lost.

The **Chairman** then called on Mr. Fry to nominate his committee.

Digitized by Google

Mr. Fry refused to do this, saying it was for the directors to propose a scheme which would be more equitable as between the two classes of shareholders.

The **Chairman** said the Board had done their best in the matter, and could not come to any other conclusion than they had done.

Matters being thus at a deadlock, it was suggested that the votes should be counted over again, the directors present voting. To this **Mr. Fry** raised no objection, saying that if on further consideration he thought it necessary he could raise the matter again at the confirmatory meeting. Upon the show of hands being again called for there were found to be 41 for the resolution and only 10 against. The resolution was therefore carried, the **Chairman** remarking that the Board had held a very large number of proxies, which, however, they had not thought it right to use.

The meeting then terminated with the customary votes of thanks, the proceedings having lasted over two hours. There will have to be a confirmatory meeting in about three weeks, and the scheme must then be approved by the Court.

WILLANS AND ROBINSON, LIMITED.

The fifth half-yearly meeting was held on Wednesday at the Cannon-street Hotel, Mr. Mark Robinson, M.I C.E. (chairman of the Company), presiding. Sir Gilbert A. Clayton East Bart., and Captain H. Riall Sankey, R.E (Ret.), M.I.C E. (directors) were also present.

The **Chairman**, in moving the adoption of the report and balance-sheet, which we published in our last issue, said he was again in a position to congratulate the shareholders in the name of the Board on the prosperous state of the Company's affairs, and doubly so when they considered the difficulties they had worked under at Thames Ditton. As they had not yet comfortably settled down at Rugby, they proposed only to pay a small dividend, but it was no inconsiderable thing to have carried over £10,000 to the reserve fund in two and a half years. They still adhered to the principle of writing off for depreciation of buildings, premises, and plant, and all those things which were wearable, £8,000 a year. With regard to the last issue of debenture stock they expressed the opinion that an issue of £75,000 would suffice, but it was strongly impressed on them by experts that a round sum of £100 000 would attract far more notice on the money market, and they felt that the growing expansion of the business warranted their doing it. Four and a half per cent. was the amount of interest estimated that they would have to pay, but they had succeeded in placing it at 4¼ without any difficulty With regard to the half-year's working, the comparatively small available balance of £10,000 was due in a large measure to the delay at Rugby in obtaining the structural steelwork which had hindered them and the contractors very considerably. The work in progress had increased from £24,000 to £33,000, and the work in stock from £23,000 to £34,000. More orders had come in than they could at present deal with, or that they were justified in dealing with, so they had limited them to the old customers and others which were considered expedient. They thought the new shops would be very convenient and commodious works, and they could confidently look forward to a very large increase in their revenue when they were in full working order. With regard to the half-yearly meetings, the directors thought it would be more advantageous to have one at Rugby every year—say, the autumn meeting at Rugby and the annual meeting in the spring in London.

The report was adopted after a few items in the balance-sheet had been questioned and explained, and the shareholders seemed to be in favour of holding one meeting at Rugby every year, but no decision was come to on this point, which will in all probability be brought forward at the next meeting.

A vote of thanks to the Chairman concluded the meeting.

ELMORE'S PATENT COPPER DEPOSITING COMPANY, LIMITED.

The report and statement of accounts of the directors of Elmore's Patent Copper Depositing Company Limited, to June 30 last states that the Board believe it to be in the interest of the Company to hold the annual meeting in London some time in October or November, when further experience of the increased output of the works will have been gained, and more definite information in regard to the copper supply scheme hereafter referred to, and other important matters, will be available. Notice of the meeting will be issued in due course. The manufacturing account yields a gross profit of £6,895, and after writing off the trading expenses and providing £500 for directors' fees, there remains a net profit from the industrial branch of the business of £4,176 available for meeting the charges (direct or indirect) entailed by the Haigh Park freehold estate. The balance of £1.522 is carried forward to next year. It should be specially observed that the revenue this year receives no benefit from the sheet license royalties which for the previous four years yielded £1 250 per annum to the credit of profit and loss. Previous years show the following balances: June 30, 1892 a loss of £8,566; June 30, 1893, a loss of £13,655; June 30, 1894, a loss of £10,435; June 30, 1895, a profit of £480, including £1,250 royalties; June 30, 1896, a profit of £1 521, exclusive of all royalties. This represents a further considerable improvement over previous years, especially in view of the fact that chiefly owing to the want of support given by the shareholders to the debenture issue in November last (the issue was subsequently withdrawn) the six months ending December 31 compare—according to an approximate balance sheet prepared by the secretary—very unfavourably with the following six months. Consequently the very satisfactory result for the year shown by the accounts arises principally from the use of £8,000 advanced by the directors at the end of 1895, and proves the statement made in the last report that the profits would rapidly augment if the company were properly furnished with capital. The manufactured stock has been valued on a very different basis from that hitherto adopted, which has been much too high. This year the approximate manufacturing cost only has been added to the cost of the raw material, without any additions for general charges. In the case of the stock of electrolytic copper, the price taken is considerably under the market price of the day, but in the case of the raw copper, which has been very well bought, the market price at June 30 has been adopted, in order that the shareholders may see the benefit of these purchases, and as the resulting profit is carried forward to next year it forms a reserve in the event of a drop in the market price. The works and plant have been maintained out of revenue in a state of thorough efficiency at a cost of £711. The output, orders, and deliveries are considerably in advance of those for the previous year, and 65 new customers are added to the books. The working expenses per ton continue to diminish with the larger amount turned out by the factory, but could be still further reduced by a larger output After an exhaustive series of comparative tests, the Board of Trade have sanctioned the use of Elmore copper tubes, of any diameter, in passenger steamers built under their survey. The Admiralty have instructed the Company to supply steam-pipes to the Portsmouth Dockyard, and the same are now under test. The Company accordingly expect to be appointed to the Admiralty list of contractors shortly. The unequalled quality of Elmore products continues to receive increasing recognition from all classes of users, both at home and abroad. A license has been granted for the manufacture of small tubes up to 4in. in diameter, subject to the payment of a satisfactory royalty per ton to this Company. Revenue from this source may be expected before the end of the current financial year. A contract to run for some years has been entered into, whereby the directors believe that the Company's raw copper supplies will be obtained on extremely favourable terms. In the past, having to pay cash for copper, and at the full market price of the day, and purchasing in small quantities, has very seriously curtailed profits. The Company has received notice from the Great Northern Railway Company of the compulsory purchase of a part of the freehold estate, and the price to be paid has been referred to arbitration. As soon as this question is settled the directors will energetically push forward the realisation of further lots. The Company in November last resolved to reduce its ordinary share capital from £182,390 to £91,195, by writing £1 off each £2 ordinary share. This step was confirmed by the High Court in April last, and the usual addition of the words "and reduced" to the title of the Company was dispensed with. The amount written off capital has been applied in the following manner: patents, £32,205; furniture, £131; buildings, etc., £2,060; stocks, £2,500; plant, £9,073; investments, £8,806; bad debts, £1 000; provision account, £1,000; profit and loss, £34,420 (£1,012 2s. in addition is written off plant and charged to the reserve account). Effect has been given to this special resolution to reduce the capital in the balance-sheet now issued New certificates will be issued to shareholders desiring to have them, but the exchange is not compulsory and is not invited. All certificates issued in future will of course be in accordance with the fact of the reduction of capital The directors earnestly ask the shareholders to thoroughly consider the Company's position. In the past very sanguine anticipations were prematurely expressed—£70,000 was distributed in dividends which should have been husbanded for trading purposes—and about £70,000 was sunk in freehold land, involving a very heavy annual charge for interest. The natural consequences were that the Company was denuded of working capital long before it could hope to overcome the initial difficulties common to every new enterprise, or to show the real merits and possibilities of the business. Only very small and most inadequate further sums of capital could be raised with the utmost difficulty and on exceedingly onerous terms; hence the business has never yet had a fair chance, although, thanks to the devotion of some of the Company's servants, a moderate success has been shown sufficient to convince every observer that the Elmore process produces an altogether unequalled finished article at a very low cost Having to deal with a very costly form of raw material at £40 to £50 a ton, as contrasted with an iron foundry where the raw material is perhaps only one-twentieth the cost of copper, a large capital is necessary for stocks in trade, and to allow the usual trade credit to customers; thus our competitors' accounts show their stocks to be many times the amount of ours, exclusive of very large cash and debtor balances. The shareholders cannot fail to see that without sufficient funds in hand the works cannot by any possibility produce large results, and all that the present directors—who share no responsibility for the mistakes made in the earlier years—could possibly hope to accomplish has been accomplished—namely, to show that a profit can be made even under the most unfavourable conditions, and thereby enable the shareholders to appreciate the real merits of the business and its potential success. The gross profit of £6,895 which has been earned this year, with very slender means, is not large if measured by ordinary standards, nevertheless the Board feel intensely pleased with the result, which amply vindicates the Elmore process, and think it will prove to the shareholders and others that the business now only requires capital on reasonable

Digitized by Google

terms to secure the success which was originally anticipated. The accounts show conclusively that the business can earn even a high rate of interest on new capital, and still leave a surplus for the original capital. The Board, therefore, are formulating a scheme for properly financing the Company, and hope to lay the details before the shareholders at an early date. Accompanying the above is a report of the auditors and of the Board on the accounts for the year ending June 30, in which it is stated the Board regret that there should be any want of unanimity among the directors in presenting the accounts, but the majority are convinced of their correctness in principle and in form, as well as being in accordance with the books and vouchers relating thereto. The points at issue, together with the views of the auditors thereon, were recently laid before a large number of the shareholders who for themselves and their friends hold more than one-half of the shares, and they all, without exception, thoroughly support the conclusions of the Board, and even went so far as to sign a request to call in an independent auditor. The matters in question have been informally referred to representatives of four first-class firms of auditors, and to other accountants, and their opinions strongly justify the views of the Board, who prefer, however, that the shareholders should be the final judges in the matter. When the present Board was formed in July, 1894, Mr. J. W. Close, C.A., Leeds, was the Company's auditor, but shortly afterwards he was asked to withdraw in favour of the Chairman's nominees—Messrs. Blackburn—and their fee for work done that year was £150, and £52. 10s. in 1895, which the chairman justified as against the complaints of the shareholders at the last general meeting on the ground that he himself being unfamiliar with accountancy matters had had to frequently consult the auditors on the accounts, but he hoped that next year the fee would be less. Accordingly, this year the Company very carefully prepared the balance-sheet, and minimised the work of the audit to the utmost, so much so that the chief auditing clerk remarked that there was very little left for them to do. Twenty-five guineas are reserved for the auditors this year, which is considered ample, but they have sent in a bill for £52. 10s. They began on July 28, and might have finished in 10 days, but it was not until September 23 that the Board got their final report. In the interval the Board called for the auditors' certificate, as the shareholders were constantly urging the issue of the accounts. The Board state that they mention these things merely to show that unpleasantness has arisen in the past, which they think must largely account for the nature and tone of the auditors' report. The text of the auditors' remarks and the Board's comments thereon are given alongside.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Dresden.—Tenders for 3,710 wooden telegraph posts for the Saxon State Railways are receivable at Dresden on October 15.

Stettin.—Tenders for the supply of telegraph posts will be received by the Administration of the Prussian State Railways at Stettin on October 17.

Bucharest.—Tenders will be received at the Mairie, Bucharest, on November 16 for two stand-by steam-engines for a water-power electric generating station at Grozavesti.

Brussels.—Among the contracts for the supply of stores to the Belgian State Railways, tenders for which are receivable at the Brussels Bourse on October 21, is lot 110, consisting of various sizes of electric light carbons.

Madrid.—Tenders will be received on October 12 by the Direccion General de Correos y Telegrafos at Madrid for the supply to the Spanish Government of 60,000 telegraph insulators. The upset price is 1 peseta (9½d.), and a 10 per cent. security will be required.

London.—Tenders will be received on October 26 for the supply of red fir telegraph poles for the Postmaster-General. Also for creosoting the poles. Particulars and forms of tender are obtainable from Mr. C. E. Stuart, controller of stores, General Post Office, London, E.C.

Villefranche-Lauragais (France).—The Municipality of Villefranche-Lauragais (Haute-Garonne) have invited competitive plans for a public water supply and electric lighting. Prizes of 1,000fr., 500fr., and 200fr. are offered, under the usual conditions, and schemes must be sent to the Mairie by October 10.

Brussels.—Tenders will be received on October 21 for the supply to the Belgian telegraphic service of (1) a quantity of galvanised iron wire, (2) various lengths of cable for riverine, submarine, and land service, and (3) a quantity of bare and insulated copper wire. No details are advertised as to the amounts required, but particulars are obtainable at the Brussels Bourse.

Werl (Germany).—The Local Authorities propose to submit to tender the construction and maintenance of an electric power and lighting generating station, and also an electric tramway from Werl to Wikede, with an eventual extension to Hamm. Further particulars will be obtainable at the Rathhaus, Werl-i.-Westf., Germany. The date for the tenders is November 3.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Brussels.—Tenders will be received on October 21, at the Bourse Brussels, for installing the electric light at the Arlon Railway Station, including the offices and works. Particulars are obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Leeds.—The Council require tenders for the supply and erection of No. 2 overhead travelling cranes for the engine-house of the tramways electricity generating station, The Calls, Leeds. Tenders, endorsed "Tender No. 8 for Cranes," must be sent in, addressed to the Town Clerk, Town Hall, Leeds, not later than 12 noon on October 13. Particulars, plans, and forms of tender may be had from the City Engineer, Municipal Buildings, Leeds, or from Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W.

Bradford.—The borough electrical engineer is prepared to receive tenders for the following meters—viz., 117 Aron meters, 86 Frager meters, 24 Edison meters, 21 Oulton and Edmondson meters. A list giving details and capacity of the above meters can be had on application to the Electricity Office, Town Hall, Bradford. Tenders are to be endorsed "Tender for Meters," and to be addressed to the Borough Electrical Engineer, Town Hall, Bradford. All meters are guaranteed to be in good condition and working order.

Madrid.—The Secretary of State for Foreign Affairs has received a despatch from H.M. Chargé d'Affaires at Madrid stating that a free public competition is announced in the *Gaceta de Madrid* of September 4 for the grant of the contract for the construction and establishment of three submarine cables to join the islands of Luzon, Panay, Negros y Cebu, in the Philippine Archipelago. Tenders must be lodged within 90 days of the publication of the conditions at the Spanish Ministry of the Colonies, accompanied by a deposit of 50,000 pesetas. The particulars received can be seen at the Commercial Department of the Foreign Office between the hours of 11 and 6.

London, W.—The Great Western Railway Company require tenders for the supply from December 1 next to November 30, 1897, of telegraph instruments, telegraph apparatus, copper wire, G.P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, carbons for electric light, telegraph poles, etc. Samples and patterns may be seen at Swindon from 12th to 23rd inst. on application at the office of the Stores Superintendent at Swindon. Specifications, with forms of tender, may be obtained at the offices of the Stores Superintendent at Swindon. Tenders, addressed to Mr. G. K. Mills, secretary, Paddington Station, London, and marked outside "Tender for Stores," will be received on or before 26th inst.

Christiania.—The Secretary of State for Foreign Affairs has received a despatch from her Majesty's Consul-General at Christiania stating that tenders are invited for the delivery of 22,000 linear metres (13 miles 1,180 yards) of rails, with the accompanying fishplates and screws, for the electric tramline to be constructed between Christiania and Holmenkollen. Tenders are to be sent in sealed envelopes, marked "Aubud," by October 15, 1896, to the Tramline's Offices, 47, Kirkeveien, Christiania, where the conditions can be procured. The rails must be delivered in Christiania by January 1, 1897. Further particulars on the subject are expected from her Majesty's Consul-General, and will be on view as soon as they have arrived at the Commercial Department of the Foreign Office any day between the hours of 11 a.m. and 6 p.m.

Morley.—The Electric Lighting Committee of the borough of Morley are prepared to receive tenders for the supply and erection of the following plant. (The whole bound up in one specification; price £2. 2s., returnable on receipt of a bona fide tender): Section A—Boiler-house plant: Lancashire boilers and fittings, feed pump, etc. Section B—Engine-house plant: steam alternators and exciters, motor alternator, accumulators, steam and exhaust pipes, valves, etc. Section C—switchboard and instruments. Section D—overhead crane. Section E—underground work: cables and stoneware culverts. Section F—transformers and switchboards. Section G—arc lamps, posts, and accessories. Section H—meters. Tenderers are at liberty to tender for any section, but not for part of a section. The ground plans of plant and specification, with terms and conditions of tenders and contract, may be obtained at the offices of Mr. Robert Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E.C., on payment of £2. 2s. for each copy, which sum will be refunded on the return of the specification, filled up with a bona fide tender. Tenders, sealed and marked "Tender for Electric Lighting," must be addressed to the town clerk, Mr. R. Borrough Hopkins, at the Town Hall, Morley (Yorks), and be delivered on or before Wednesday, October 14.

RESULTS OF TENDERS.

Belfast.—The Corporation have accepted the tender of the Acme Gas-Engine Company for a new engine and dynamo for the electric light station.

Digitized by Google

Down.—The Governors of the District Asylum have accepted the tender of Messrs. Wm. Coates and Son, Belfast, to fit the asylum with electric bells at a cost of £20.

Newcastle.—The Arniston Coal Company have contracted with Messrs. Ernest Scott and Mountain, Limited, electrical and general engineers, for the supply of an electric pumping plant of considerable size for their colliery.

Watford.—The Board of Guardians have accepted the offer of the National Telephone Company to fit up telephonic communication between the workhouse, Dr. King's house, and the relieving officer's house for £10. 10s.

Birmingham.—The Corporation have accepted the tender of Messrs. Mavor and Coulson, of Glasgow, at about £8,000 (the lowest tender received) for the supply and construction of electric lighting plant at the new meat market. Messrs. Lea and Thornbury were the consulting electrical engineers.

Cheltenham.—Tenders for 20 electric lamp pillars, as per design, for the Promenade were received as follow: Messrs. Hardy and Padmore, Worcester Foundry, fitted with plain wrought-iron tubes, £12. 17s. 6d. each, delivered at Cheltenham; Messrs. Andrew Handyside and Co., Limited, Britannia Ironworks, Derby, £18. 15s. each, with tubes, delivered at Cheltenham; McDowall, Steven, and Co., Limited, Milton Ironworks, Glasgow, £11. 15s. each, without tubes, delivered at Cheltenham. The Corporation have accepted the tender of Messrs. Hardy and Padmore.

BUSINESS NOTES.

Westminster.—The St. George's Vestry have resolved to light the stables by electricity.

Great Northern Telegraph Company.—The receipts for the month of September were £24,000.

Eccles.—The Town Council are about to experiment with incandescent electric lamps for street-lighting.

Crewe.—The new isolation hospital is to be lighted by electricity so as to increase the accommodation for patients.

Dover.—Arrangements are being made for lighting the pit which is being sunk by the Kent Coalfields Syndicate near Dover, with electric light.

Garthorpe.—It is expected that the extension of the telegraph from Crowle to Garthorpe will be completed the early part of the present month.

West India and Panama Telegraph Company.—For the two weeks ended September 30 the receipts were £1,639, as against £1,720 for the corresponding period of 1895.

Ramsbottom.—At the monthly meeting of the Urban District Council, a committee was appointed to take into consideration the advisability of lighting the town by electricity.

Wilmslow.—At the meeting of the District Council some discussion took place with reference to the electric light, and it was ultimately decided to apply for a provisional order.

Astrakhan.—According to the *Elektrotechnischer Anzeiger* the construction and working of the Astrakhan electric tramways are to be undertaken by a company domiciled in Belgium.

Oriental Telephone and Electric Company, Limited.—The directors have resolved to pay an interim dividend of 4d. per share, free of in ome tax at the end of the current month.

Woking Sanitary Electric Laundry Company, Limited.—This Company has just been floated, with a capital of £10,000, in £1 shares. The object is sufficiently indicated by the title. Registered without articles of association.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending October 4 amounted to £1,184, as compared with £1,088 in the corresponding week of the previous year, being an increase of £96.

Hampstead.—The street-lighting experiment referred to at a recent meeting of the Vestry by Mr. C. H. Reed, chairman of the Lighting Committee, is, we are informed, not with incandescent gas, but with incandescent electric light.

Bury.—At the meeting of the Town Council it was stated that the electric installation would be complete by the middle of the present month, and it was resolved that the principal centres of the town should be lighted by electricity.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending October 2 were £2 203. 19s. 5d., compared with £1,942 19s. 10d. for the corresponding period of last year, being an increase of £260. 19s. 7d.

Gloucester.—The town clerk laid before the last City Council meeting a Queen's printer's copy of the Electric Lighting Order Confirmation (No. 1) Act, 1895, confirming (*inter alia*) the Gloucester Corporation Electric Supply Order, 1895.

Eastern and South African Telegraph Company.—The payment by warrants on November 2 is announced of interest on the 4 per cent. Mauritius subsidy debentures. The transfer books will be closed from October 27 to November 2 inclusive.

Stockton.—At a meeting of the Tees Conservancy, Mr. Hanson, chairman of the Graving Committee, stated that a visit had been paid to the Tyne to inspect the electric light installations at the graving docks there, and a report would be made and submitted.

Bristol.—The report of the Electrical Committee, recommending the acceptance of a contract for the extension of the central station, at a cost of £16,974, was adopted at the meeting of the Town Council. The committee had estimated the cost at £16,500.

Grantown (Elginshire).—The ratepayers are considering the advisability of lighting the town with electricity. They have had a scheme before them estimating the necessary outlay at £4,500.

Canadian Pacific Railway Strike.—The backbone of the Canadian Pacific Railway telegraphists' strike seems effectually broken, and the strikers are returning to their posts all along the line. The company's freight as well as passenger service is now working well.

Eastern Telegraph Company. — Payment by warrants on November 2 of interest for the half-year ending October 31 on the 4 per cent. mortgage debenture stock is announced. The transfer books will be closed from October 27 to November 2, both days inclusive.

Anglo-American Telegraph Company.—The directors have resolved to declare an interim dividend for the quarter ending September 30 of 12s. per cent. on the ordinary stock and of £1. 4s. per cent. on the preferred stock, less income tax, placing £6,000 to the credit of the renewal fund.

City and South London Railway.—The returns for the week ended October 4 were £903, compared with £887 for the corresponding period of last year, being an increase of £16. The total receipts for the half-year 1896 were £12,715, compared with £11,857 last year, being an increase of £858.

Lytham.—In the Streets and Beach Committee minutes read at the meeting of the District Council, a letter was incorporated from the solicitors of the Blackpool Tramways Company urging objections to the alterations in the agreement. A resolution was passed that the agreement be approved.

Wakefield.—At a meeting of the Tradesmen's Association a resolution was passed instructing the secretary to communicate with the Corporation in relation to the electric light, asking for information as to when the inhabitants may reasonably expect to be supplied therewith, and upon what terms.

Japan.—The Japanese telephone system is about to be greatly extended. In Tokio there are 2,000 subscribers, and more than 2,600 applicants are waiting. The Government wants to establish electric services of various kinds on a large scale, and a commission is now in the United States studying the subject.

Hastings.—The Town Council have given their assent to a notice from the secretary of the Hastings and St. Leonards-on-Sea Electric Light Company, Limited, of the intention of the company to extend their main in Church-road and De Cham-road, subject to the works being carried out to the satisfaction of the borough engineer.

Windermere.—At the meeting of the Council the clerk brought up the matter of agreement of the Council with the electric light company. The difficulty as to the price of the lamps, whether they should be 30s. or 38s., was still pending. It was left to the Highway Committee to settle, and power was given to sign the agreement.

Edison and Swan United Electric Light Company, Limited.—The following alterations have been made in the staff of this Company: Mr. C. M. Downie has resigned his office of sales superintendent and Mr. Edward Coote has been appointed general manager in his place. Mr. J. Cooper has been appointed as accountant in the place of Mr. Edward Coote.

Ramsey.—At a meeting of the Town Commissioners it was decided to invite two companies who are competing for powers to construct an electric railway from Laxey to Ramsey to lay their respective schemes before the Board, so that the Commissioners may judge which to support when the matter comes before the Tynwald Court on the 28th inst.

Swansea Copper.—Messrs. Richardson and Co.'s (Copper Ore Wharves, Swansea) quarterly circular has just been issued. It shows that the Swansea imports of copper produce for the quarter ending September 30 were: ore, 33,220 tons; regulus, 8,678 tons; copper, 612 tons; and precipitate, 5,394 tons. The exports in the same period were 1,159 tons 10cwt. 20lb.

Llanelly.—At a meeting of the Highway Committee of the Borough Council a letter was received from Mr. J. C. Howell, electrical engineer, offering to light up Station-road by electricity for a few nights at his own expense, in order to give a sample of how the work of electrically lighting the whole town would be done if entrusted to his care. After a short discussion, the offer was accepted.

Tunbridge Wells.—Arrangements have been made for a continuous supply of electric light starting from October 12. The total number of lamps will soon reach 10,000, and no less than 950 lamps were put on during September, the consumers now numbering 190. One of the new alternators is being used, and is already overloaded, so that the needed enlargement is being pushed on as quickly as possible.

Books Received.—We have to acknowledge from Macmillan and Co. the receipt of "The Elements of Electro-chemistry." This is a translation by Mr. W. R. Whitney of Prof. Max Le Blanc's work on the subject. We have also received from G Philip and Son "A Systematic Course of Geometrical Drawing," by Mr. T. A. Ford. We hope to give a further notice of these two books shortly.

Altrincham.—At the meeting of the District Council the minutes of a special meeting approving of an electric tramway were approved. At the same time the Council were strongly opposed to the overhead system, and covenanted that there should be an express understanding that the Council would be secured the option of purchase of that portion of the undertaking within the Altrincham section.

Digitized by Google

Chichester.—A meeting has been held for the purpose of considering a communication from the National Telephone Company expressing willingness, should a sufficient number of subscribers be obtained, to extend their trunk line to Chichester, and thus bring the city into telephonic communication with the rest of the country. A small committee was appointed to consider the whole question and report at a subsequent meeting.

Phaeton Electrical Company.—We are informed that this Company will open on October 15 a branch office in London at 61 and 62, Watling-street, Queen Victoria street, E C, and as soon as the necessary steps can be taken the branch will be formed into a limited company. In the meantime Messrs. Krupka and Jacoby will act as managers of the branch, and as soon as the company is formed they will be appointed the managing directors.

Audenshaw.—The District Council have consented to the laying by the Manchester Carriage Company of a single line of tramway within the Council's district on Droylsden-road, with the necessary passing places, commencing from the boundary of the district at Williamson-lane to the junction of the company's line at Ashton Old-road, and have also assented to the company's application for a special Act or provisional order, *inter alia*, for the purposes named.

Dudley.—The Lighting Committee's report containing a recommendation that a provisional order be applied for to enable the Corporation to supply electricity for lighting and other purposes was adopted at the Town Council meeting. Alderman G. Bagott, in moving the adoption of the report, said he found that throughout England 96 similar applications had been made, and in about 70 cases provisional orders had been obtained.

Leeds.—The City Council have resolved to apply for powers in the ensuing session of Parliament for the extension of the tramways in various parts of the city, including Meadow-lane, Oldfield-lane, Aire street, Dewsbury-road, Hunslet Moor-road, Church-street, East-parade, Great George street, Park-lane, Cardigan-road, St. Michael's-road, East-street, and Upper Accommodation-road. The committee propose to take the trams into all the thickly-populated parts of the city.

Bombay.—We understand that the new "Lakhmi Vilas" Palace of H.H. the Gaekwar of Baroda, a description of which lately formed the subject of an exhaustive paper read before the Institute of Architects, is to be lighted throughout by electricity, and that the contract has been entrusted to a Bombay firm. The lighting of his Highness's Makarpura Palace has not long been completed, and the above will therefore be the second of his Highness's palaces to be fitted with the electric light.

Changes of Address.—Messrs. Ernest Scott and Mountain, Limited, of Newcastle-on-Tyne, have removed their London offices from 5, Crown-court, to larger offices at 20, New Bridge-street, Blackfriars, E C.—Dr John Attfield, F.R S., having resigned the professorship of practical chemistry to the Pharmaceutical Society of Great Britain, after a 34 years' tenure, has left 17, Bloomsbury-square, and continues his professional practice as a chemical consultant and analyst at 111, Temple-chambers, London, E.C.

Southport.—The electric lighting is being taken up very rapidly, and there is a probability before the winter is over that the demand will have overtaken the power of production. Since the exhibition, which was held in the Cambridge Hall a few weeks ago, 20 new customers have been added to the list, and of these five require 14 arc lamps. At the present time there are 170 consumers, representing about 12 000 8-c.p. lamps, in addition to the arc lights in the street, which amount to 1,200 more. The current is also being taken for motive power.

Appointment Vacant.—The Electric Lighting Committee invite applications for the post of electrician-in charge in the electric supply station, where there are two vacancies. Applicants must have held similar positions in high-tension alternating stations. Salary £2 per week. Applications, on foolscap paper, stating age, experience, and accompanied by copies of not more than three recent testimonials (which will not be returned), must be sent to Mr. F. C. Lloyd, town clerk, Town Hall, Huddersfield, by 10th inst., endorsed "Electrician-in-Charge"

Kensington.—The Vestry received 132 applications for the post of resident electrical engineer. The committee submitted the names of the following for final selection: Mr. J. G. Bell, of Manchester; Mr. H. W. Couzens, of Taunton; and Mr. J. Pilling, of Bolton. Mr. Bell was elected by a large majority. The Works Committee report that during the month of August 19 miles 1,690 yards of overhead wire and 200 yards of steel wire have been fixed; five new poles and one ground pole erected; 8 miles 320 yards of wire removed, and two poles removed.

Bray (Wicklow).—A letter was read at the meeting of the Commissioners from Messrs. Molloy and Molloy, solicitors, informing the Commissioners that the proposed pier and the electric tramway scheme were promoted by different gentlemen. Sir Henry Cochrane said it was understood that the same gentlemen were promoting the schemes. Messrs. Molloy and Molloy were acting as solicitors for both schemes. Mr. Cuthbert said he hoped they would not consent to have tramways run through the streets. The letter was marked "read," and the subject dropped.

The Trocadero Restaurant.—The electric light has been installed throughout this building. The new conduit system of wiring has been used, the whole of the cables and wires being drawn into specially-prepared wrought-iron tubes insulated inside and provided with inspection tubes as convenience dictates. The work has been carried out by Messrs. Strode and Co., and this is one of the largest buildings in London fitted with the system. The General Electric Company, Limited, call our attention to many other installations in hand, or recently finished, in which insulating tubes are being used.

Wallasey.—Mr. R. M'Geoch, in moving the adoption of the Gas and Water Committee's minutes at the District Council meeting, referred with satisfaction to an agreement effected with the Electric Free Wiring Syndicate, Limited, to supply all consumers of electric light within the district with initial charge. In the course of a discussion which ensued it was stated that the price to be charged for the light per Board of Trade unit would be 8d. Of this sum, ¾d. would be paid by the Council to the syndicate supplying the connections and fittings. The supply of light might be expected to commence about the end of the present month.

Brighton.—Notwithstanding the very heavy seas that accompanied last week's gale, we are informed that not the slightest damage was done to the permanent way of the sea-going car. On Thursday afternoon several trial trips were made, over 100 visitors being conveyed on each trip. The appearance and running of the car give the greatest satisfaction to everyone. With the exception of a small amount of concrete work, everything is now complete. The Town Council have adopted the report of the Works Committee recommending that permission be granted to the National Telephone Company to lay wires underground in various streets.

Light Railways.—The movement for the construction of light railways is making considerable progress in Germany. The number of existing and projected lines in Prussia is, according to the latest returns, no less than 167. Of these lines 103 were authorised by the Act of July, 1892, and 49 have not yet been constructed. Sixty of the lines are designed both for goods and passengers. The standard gauge exists on 39 lines, the 1 metre gauge on 39, the ·75 metre on 11, and ·60 metre on 7 of the systems. The lines worked by locomotives are 67 in number, 23 are worked by electricity, and 11 by horses, while 2 are worked partly by locomotive power and partly by horses.

Tonbridge.—Mr. F. Hastings Medhurst, consulting electrical engineer, has recently visited the town for the purpose of obtaining particulars for his report to the Council as to the best methods of lighting the town by electricity. He was accompanied by the clerk to the Council and the surveyor in visiting various parts of the town which it is thought could be profitably lighted by electricity, and in the end he expressed the hope that he should be able to present his report to the Council within a fortnight. We understand that a special meeting of the Council will be held on the 19th inst. for the purpose of deciding whether or not a provisional order shall be applied for in the ensuing session of Parliament.

Hanley.—The Town Council have decided on a report of the borough surveyor to extend the electric lighting in Newcastle-road as far as Mr. Twyford's works; also, owing to the increased demand for electricity, and there being every probability of the present capacity being fully taken up before September, 1897, to take advantage of the clause in the agreement with Messrs. Ferranti for the provision of a second engine, and that steps be taken to prepare a further application to the Local Government Board for borrowing powers. The ex-Mayor stated that the electric installation was paying its way, although the price had been reduced from 6d. to 5d. per unit. The salaries of the electrical engineers have been raised.

Another Metropolitan Electric Railway.—The Metropolitan District Railway Shareholders' Association write to the daily papers saying that a scheme has been approved by the directors for the construction of two deep-level tunnels for up and down service of express electric trains between Earl's Court and Mansion House, with an intermediate station at Charing Cross. The proposals for financing the scheme are as follows: the association will advance one million at 4 per cent. on the following terms—association to receive no interest until existing preference dividend paid in full. Association to provide all preliminary expenses. Association to receive a deferred bonus of one-half the profits after existing £2,250,000 ordinary stock has received a dividend of 5 per cent.

Portsmouth.—The Town Council have adopted the recommendation of the Electric Light Committee to let out on hire electric motors and electric ovens to consumers at 15 per cent. on the cost price. The Corporation have had some troubles to contend with in the shape of mishaps with the electric light, fuses blowing out, etc. The cause of the latter was due to the action of certain consumers who have made considerable extensions in the electric lighting of their premises without obtaining the sanction or even informing the Electric Lighting Committee. The demand for the current just now is extraordinary, and during the quarter just ended two and a half times more has been sold than in the corresponding quarter of last year. At a meeting of the Electric Lighting Sub-Committee, it was decided to recommend the full committee to provide three additional transformers to reduce the strain upon the present instruments.

Sunbury.—Wallace Williams, 13 years of age, was recently charged at Sunbury Police Court with breaking and entering a signal-box on the London and South-Western Railway, and stealing therefrom an electric semaphore and repeater, value £5. Mr. R. Sykes, solicitor, prosecuted. The prisoner was arrested on suspicion, and he admitted that he broke into the signal-box and stole the instrument. He said he effected an entrance to the box with a chisel, and cut the wires attached to the semaphore with a pair of pliers. A quantity of guttapercha wire, a battery, and other instruments were also found by the police, and prisoner admitted having stolen these also from the railway. Inspector Mason, of the National Society for the Prevention of Cruelty to Children, stated the boy was regarded as not being half right

Digitized by Google

in his mind. The prisoner was remanded to the Kingston Workhouse for a week to see what could be done in his behalf.

Bolton.—At a meeting of the Gas and Electricity Committee the question of laying electric cables and supplying electricity to the Park Sawmills, Spa-road, was referred to the chairman and engineer. The engineer reported on the unsatisfactory working of the accumulators at the electricity works and correspondence on the subject with the makers. The matter was referred to the chairman and engineer for them to confer with the town clerk. A resolution was passed informing the General Purposes Parliamentary Sub-Committee that further statutory powers were required by the electricity department for the supply of electricity for tramways traction and for purposes outside the borough. The report was approved. The Town Council have decided to apply for powers to borrow £30,000 for electricity purposes.

Fulham.—With reference to the offer of the County of London and Brush Provincial Electric Lighting Company to submit a draft agreement and definite prices for the purpose of the Vestry transferring their provisional order to them, the Electric Lighting Committee recommended at the last Vestry meeting that, before receiving terms from any company, the clerk communicate with the metropolitan parishes and provincial towns who have taken up the electric light with a view to obtain information as to the terms upon which they have obtained provisional orders or have allowed them to be taken over by electric lighting companies. Having considered a letter from the County of London and Brush Provincial Electric Lighting Company, Limited, making formal application for the consent of the Vestry to their proposed provisional order, they recommended that the clerk be instructed to inform the company that the Vestry cannot consent to their proposed order, they having already decided to oppose their application.

Leatherhead.—At the Urban District Council meeting Mr. Dearle moved "That a memorial be presented by this Council to the Board of Trade applying for a provisional order under the Electric Lighting Act, 1882, to authorise this Council to supply electricity for any public or private purposes within the Leatherhead urban district." His reason for doing so, he said, was that they had been given to understand that a company which was being formed was about to apply for similar powers, and it was thought by some members of the Council advisable to secure such order themselves, thus preventing any company coming in. It did not follow, however, that they would be bound to act upon the order, and he wished it to be understood that he was not taking this course with any antagonistic feeling towards the present system of lighting. Mr. Howell thought it would be better for the matter to be referred to the General Purposes Committee, and he proposed, as an amendment, that this should be done. The amendment was eventually carried.

The City and Waterloo Electric Railway.—The construction of this railway is making steady progress, and the up line on the Waterloo side of the river is within a few feet of its terminus. Excavation is now going on under the approach to the Windsor line, and will soon reach the station, which has for some time past been in process of construction under the South-Western Company's station at Waterloo. The down line is not so far advanced. It has reached a point about 650ft. from the terminus, and there has come to a temporary stop. Between this point and Waterloo the South-Eastern Company have required the underpinning of the viaduct at Cross-street, and as this had to be done the engineers of the new line thought it expedient to sink a temporary shaft here and to work from this shaft backwards to meet the completed portion of the down line. On the City side the work is so far advanced that it is expected that in February the up line will be complete from Waterloo to the City station, which will be under the road between Queen-street and Bucklersbury.

Belfast.—At the meeting of the Corporation Councillor Andrews moved the adoption of the report of the Electric Committee, which stated that the committee had accepted the tender of the Acme Gas-Engine Company for a new engine and dynamo for the station. The committee had under consideration the advisability of putting down a much more extensive installation, and hope to report fully on the question at an early date. Councillor Andrews said it had been found necessary to add to the present gas-driven supply one Acme gas-engine, with dynamo, because they had seen that without taking any new customers they would in a week of heavy lighting have required their full potential output, unless they added to their plant. They had not yet got a vote in the Corporation for the steam-driven station, but a report would be brought forward when the Corporation considered the estimates of next year. In reply to Councillor Young, Councillor Andrews said the cost of the engine and the dynamo was £1,125. If they chose to remove the dynamos they could very well be driven by steam. The report was agreed to.

Exeter.—It was recommended by the Electric Light Committee at the meeting of the City Council that tenders be obtained for the instruments required for the equipment of the station, and that the surveyor be authorised to make arrangements with Messrs. Wheaton and Messrs. Hepworth for renting portions of their respective cellars for use as transformer stations. A letter was read from the surveyor to the General Post Office asking to be notified what special terms the Council were prepared to offer for the use of the electric light in Exeter Post Office, and the committee recommended that the terms offered be the same as those offered to the Devon and Exeter Hospital. The city surveyor reported that the remainder of the stores formerly belonging to the electric light company, of which the Council had purchased a portion, had been offered to him for a sum of £26. The committee recommended that the stores be purchased at the price named. They also recommended that the city surveyor be instructed to report upon the supply of power by electricity and the sums which should be charged therefor. The report was adopted.

Edinburgh.—Mr. Mathew Buchan, electrician, Portobello, has recently returned from the French Government arsenal at Cherbourg, where he had been sent by the Thomson Electric Welding Company, U.S.A., proprietors of the "Lemp" process of electric annealing of armour-plate, of which the surface has been hardened by the Harvey process. The apparatus having been installed under Mr. Buchan's supervision, a series of experiments were then carried out in presence of the French Government officials. It is stated that all the experiments were highly satisfactory, and demonstrated the value of the invention to modern naval construction. The *Edinburgh Evening Dispatch*, to which we are indebted for the above paragraph, also publishes a rough sketch of the annealing apparatus. The principle, of course, is the local heating of a portion of the surface of the plate by a heavy current applied by two copper contact pieces. The heating of course softens the surface of the plate, so that it will take the drill or other tool. The current used is an alternating one, and the secondary of the transformer which supplies the current to the contact-pieces has but one turn.

London.—At the meeting of St. James's Vestry a letter was read from Messrs. Moore and Burgess, of St. James's Hall, protesting against the dilatory manner in which the work in connection with the laying of electric mains was being carried out in the parish. Messrs. Moore and Burgess stated that in one week their receipts showed a diminution of £100, and that they expected that the coming week would show a larger decrease. The surveyor explained that the work had been delayed in consequence of the bad weather, and that there had been no unnecessary delay as far as the Vestry was concerned. He expected that by the end of October the whole parish would be lighted by electricity. The Electric Lighting Committee have reported that they had considered the question as to the desirability of obtaining guard-posts to the refuges now in the course of construction for the public arc lamps, and with a view of preventing any delay in the installation of the electric light in the public thoroughfares, an order had been given to Messrs. Freeman and Co., the firm agreeing to provide 100 guard-posts, according to pattern, at £3. 12s. each. Mr. Cheney complained that no other firm had been asked to tender, but no action was taken.

Catalogues.—Messrs. Ames, Garrard, and Co., workers in metal and engineers, of Goldney-place, London, W., have adopted a very sensible idea in their catalogue. They do not seek to utilise every available square inch of paper with minute diagrams and letterpress; on the contrary, the catalogue consists of a few pages containing a few illustrations, on one side of the paper only, of electroliers, brackets, and pendants, which are more in the nature of specimens (though a price-list is given at the end), for their aim is rather to design specially for each client wherever possible than to force upon his notice an endless array of stock patterns. The samples given in the catalogue are of very graceful and artistic design.—We have also received a copy of Catalogue B of the J. H. McEwen Manufacturing Company from the Stewart Electrical Syndicate, Limited, manufacturers' agents, 103, New Oxford street, W.C. It contains a dissertation on continuous current generators, pointing out the leading defects of the ordinary methods of design as they appear to Messrs. McEwen, and then goes on to describe how all these defects are claimed to be remedied in the Thompson-Ryan dynamo. The field magnets and the armature are fully described and illustrated, and the catalogue itself is a most creditable production.

Reading.—A letter was read at the Town Council meeting from the tramways company submitting an application for certain alterations and extensions of the tramways, together with the reconstruction of the present lines in order to the whole being worked by electricity. The letter also contained an invitation to the Council to visit Bristol to inspect one of the most recent installations of electric traction, which has now been in successful operation for nearly 12 months; and also offered to defray the expenses of the visit. The Mayor said they would agree that there were a few serious questions underlying the application, and it would be unwise to take action without carefully considering what it might lead to. He therefore moved that the matter be referred to a committee of the whole Council. The motion was carried. It was resolved to give notice to the Reading Electric Supply Company, in accordance with Clause 14 of the Reading Electric Supply Order, 1893, that the Corporation desire in future to exercise or discharge the powers and duties of the company in relation to the works of filling-in, reinstating, and making good all streets, bridges, sewers, drains, tunnels, or other works vested in or under the control or management of the Corporation which may be broken up by the company for the purposes of the above-mentioned order.

Nottingham.—There was a large attendance of interested visitors to Messrs. E. Reader and Son's Phœnix Works, Cremorne-street, Nottingham, the other day to see two sets of compound-condensing high speed engines for driving electric light at work. The engines, which indicate 150 h.p., and are capable of supplying no less than 1,600 lights each, have been built to order, and at the end of the week will be transhipped to the city of Charkow (Kharkof), in Russia. The invention, which is of a compact and at the same time of a most substantial character, and of the most approved type, is one likely to be very extensively requisitioned. It is capable of making 230 revolutions per minute, and will drive direct on to the dynamo. It is certainly a new departure in the engineering line for Nottingham; in fact, we believe that these

Digitized by Google

are the first high-speed engines for electric lighting purposes which have been manufactured in the town. It is, therefore, satisfactory to learn that the prospects of a development of this branch are extremely favourable; indeed, Messrs. Reader and Sons are now about to put down two triple-expansion engines to indicate 600 h.p. and 150 revolutions, these also being destined for Russia. The firm in question are taking the branch up thoroughly, and, we are given to understand, intend to make this one of the largest departments of their business.

Cork.—At a special meeting of the Corporation the following minutes of the Electric Lighting Committee of September 18, called to consider and report on two tenders for transfer of the powers conferred on the Corporation by the electric lighting provisional order, were passed: "The report on the tenders by Messrs. Kincaid, Waller, and Manville showed that the prices quoted for current by the No. 2 tender (Cork Electrical Tramway Company) are more advantageous on the whole than that of No. 1 (London and Brush Company), even with the percentage of profits offered by the latter, that the first installation of plant, proposed by the tramways company, is more favourable than that of the Brush Company, while the capital to be expended in the first instance is one-third greater. That the proposal of the Brush Company as to acquisition of the undertaking by the Corporation is at variance with the conditions laid down, while the latter are tacitly accepted by the tramways company, that on the whole the latter company's proposal is far more advantageous for the Corporation than the other, and that the question of the Corporation exercising the powers under the provisional order was a matter for themselves to consider. Councillor Farrington proposed that the tender (No. 2) of the Cork Electrical Tramways Company be recommended for acceptance by the Council. Councillor Cronin seconded the motion." The motion was carried after certain modifications and additions had been made.

Pelsall.—At the Parish Council meeting, the Chairman said that in accordance with the wish of the Council a committee had met to consider the lighting question. The matter was carefully gone into, and it was estimated that to light the parish by means of electric light it would cost nearly £2,000, which meant a total cost to the parish of £250 per annum; but it was also estimated that there would be an income of £100 a year, so that for public lighting it would cost them £150 a year. They next considered the question of lighting by gas, and it was thought that this would be the cheapest means if they could meet the Rushall Parish Council as regards bringing the mains down Rushall-lane. To lay down the mains it would cost £400, and they would have to pay interest on this sum. The total cost would be about £88 10s. per annum. The next question was the lighting by oil, and it was estimated that this would cost something like £65 a year. Mr. Bickley asked if they had got any estimate of the cost of laying down of gas plant of their own. The Chairman said that they had not. Mr. Bickley said that if Brownhills could have a gas company he did not see why they should not. Mr. Binns said that the gas supplied by these small companies was of a very poor character. The Chairman said that these small companies could not supply gas at the price the Walsall Corporation could. The Corporation supplied gas at 2s. 7d. a thousand, whilst the Brownhills Company charged half as much again. Mr. Bickley said that that was all very well for private consumers, but it would not cost much more to the Parish Council if they had to pay interest on the outlay on the mains. The Chairman said he was of opinion that the place would not progress very much until they had some light. It was resolved that the committee be requested to obtain further information on the question.

Cheltenham.—A discussion took place at the Town Council meeting on the electric tramway question. Mr. Feeney, Alderman Drew, and the Deputy-Mayor expressed the fear that the tramway would practically be a railway, seeing that the gauge to be used was proposed to be 4ft. 8½in. in width—viz , the same as that of the Great Western and Midland Railway Companies, and that—so they now learnt for the first time—goods traffic was to pass over the line. The speakers feared the garden character of the town would be altered by allowing such traffic to be taken through its streets. Dr. Ward-Humphreys, Alderman Norman, Mr. Lawrence, and Mr. Parsonage pointed out these fears were groundless. It was reported that Mr. Lumley, on behalf of Mr. Nevins, the promoter of the tramway, raised an objection to a clause in the agreement prepared by the town clerk that the provisional order to be obtained should contain a proviso empowering the Corporation to purchase the undertaking at the end of a specified period. The town clerk replied that the Council considered that such a clause should be inserted, and this was agreed to. The electrical engineer reported that good progress continued to be made with the works and mains extensions—the Suffolk-square and Cambray extensions being complete, and a large part of the arc lighting mains laid; that the High-street extension was well in hand and that the remaining arc light mains were being laid; that he expected that the new steam alternator would be ready for work within a few days; that Mr. Herbert had applied for a service to the Imperial Rooms, and that this could been given from a low-pressure cable to be laid along the road behind the Promenade ornamental garden at a cost of about £50. It was decided to lay the service to the Imperial Rooms as suggested, and also to place an arc lamp in the open space near the Norwood Arms in continuation of the lighting in the Bath-road already ordered.

Blackburn.—The Town Council have resolved to apply to the Local Government Board for sanction to borrow £10,000 for laying down generating plant and equipping electric tramways in Blackburn. The Corporation will supply electric current to the tramways company at 3d. per unit on car mileage of 120,000 car miles, and 2d. per unit beyond that distance. Estimates show an annual profit of £800 to the Corporation, and a saving to the tramway company over the present methods of working of £1,400 per annum. The following minutes of the Gas Committee were adopted: "That the committee has considered the report of Mr. E. M. Lacy, A.M.I.C.E , on the application of the Blackburn Corporation Tramways Company, Limited, as to the terms upon which the Corporation would be willing to erect all necessary plant for working the Preston New-road and Witton sections of the tramway with electricity (the company having substituted the Witton system for the Cemetery section), and resolved: (1) That it be a recommendation to the Town Council to agree to the substitution of electric traction on the Preston New-road and Witton sections of the tramways, in lieu of animal power, and pursuant to the provisions of the Blackburn Improvement Act, 1882, to sanction electricity as a motive power on these tramways. (2) That the Corporation agree to provide the necessary generating plant and overhead wires and posts (the company providing the electric cars and motors), and to supply the company with current at the following prices—namely, on a car mileage of 120,000 miles, 3d. per unit; exceeding 120,000 miles, 3d. per unit on 120,000 miles, and 2d. per unit for every car mile above 120,000. The company to pay for a minimum car mileage of 100,000 at 3d. per unit. (3) That an annual fixed sum be charged to the tramways company for the maintenance of the overhead wires and of the electric motors and other electrical machinery used on the cars. (4) That it be a recommendation to the Town Council to apply to the Local Government Board for sanction to borrow the sum of £10,000 for generating plant, overhead wires, and posts. (5) That it be an instruction to the town clerk to prepare a formal agreement to be entered into between the company and the Corporation to carry out the arrangement, including all necessary details."

Birmingham.—The company promoted by Messrs. Mackenzie and Ross to take over the bulk of the Birmingham tramways has now been formed. The company has been registered with a capital of £1,000,000 in £5 shares. The number of directors is not to be less than five nor more than nine; the subscribers are to appoint the first; qualification, £1,000; remuneration, £1,250 per annum divided. The capital is divided into 80,000 5 per cent. preference shares of £5 each and 120,000 ordinary shares of £5 each. The present issue is 40 000 preference 5 per cent. shares of £5 each, fully paid; 60,000 ordinary shares of £5 each; and 3,000 mortgage debentures 4 per cent. of £100 each. This makes a total of £800 000 The preference shares are entitled to a cumulative preferential dividend of 5 per cent. per annum. They are also preferred as to capital. The mortgage debentures are repayable in 1917, and are limited to 500,000, being one-half of the capital. They will be secured by a trust deed constituting a first charge on the property of the entire undertaking. The trustees for the debenture-holders are Mr. J. A. Christie, Leamington, and Mr. James Ross, Canada. The board of directors has been constituted as follows: William Mackenzie, president of the Toronto Railway Company; James Ross, vice-president and managing director of the Montreal Street Railway Company; Henry Buckley, chairman of the Birmingham Electric Supply Company; and William Neale, chairman of the Birmingham Central Tramways Company. Mr. W. Holmden is the secretary, and Messrs. Millward and Co. solicitors. The company have acquired the Birmingham Central Tramways Company as a going concern for £485,000, and certain other payments. The existing tramways of the Birmingham Central Tramways Company consist approximately of 27 miles of single line, held upon several leases from the Corporation, terminating in 1907 and 1911 respectively, and of 14½ miles of single line outside the city boundary, held upon the usual conditions imposed by the Tramways Act of 1870. Terms have been approved by the city authorities for the surrender of the existing leases, and the grant of new leases for 21 years on a satisfactory basis as to the rental and for the substitution of an improved motive power. As to the future scheme nothing is yet settled, but the idea of the company is to link the existing lines, so that cars in connection may be taken from one end of the city to the other.

Telephones in Scotland.—Since the transference of the telephone trunk wires from the National Telephone Company to the Post Office many complants have been heard from manufacturers and other subscribers with regard to the inconvenience of the new system. One of the chief matters of complaint is that of the difficulty of getting connected, the fact that now four connections have to be made instead of two as formerly. causing great delay. Another grievance, which in many cases becomes an intolerable nuisance, is the "three-minute limit." In Arbroath the feeling of dissatisfaction with the new arrangements is so strong that most of the principal subscribers, rather than submit to the worry and inconvenience now being experienced in using the trunk lines, are threatening to have the instruments immediately cleared out of their establishments. The main objection to the new system is the rule which obtains, and which it is generally agreed is carried out by the operators with needless and exasperating officialism, that at the end of three minutes the connection ceases. There is a general complaint as to the length of time that is taken to effect the trunk line connections, and subscribers also find greater difficulty than formerly of hearing and making themselves heard over the trunk wires. Upon the whole the new system is looked upon with the utmost disfavour. At the meeting of the Fifeshire Standing Joint Committee Captain Bremner said that since the telephone system had been taken over by the Post Office authorities their service had simply been in a total state of disorganisation. In fact, and put shortly, he would

Digitized by Google

not recommend the committee to continue the telephone system as at present. It was not worth the candle. The Chairman remarked that there was a general complaint all over the country regarding the way the telephone system was now worked, and it was simply intolerable. He recommended that a strong representation should be made to the Government authorities. Mr. Cathcart remarked that the report from Captain Bremner was that the telephone was practically useless, and he thought they should give it up altogether. Sir Ralph Anstruther coincided, and approved consideration of the offers for a telephone system. The Chairman, in reply to Mr. R. Glass, stated that the estimated cost was £1,600 or £1,700. Mr. David Lees said that in the arrangement with the Telephone Company the Council reserved the right to put wires on their poles, and he asked if that would be allowed now. The Chairman replied that the Post Office authorities had intimated that they would not allow the poles to be touched. The committee were instructed to consider the offers and report.

Dundee.—The members of the Harbour Trust have been discussing the best means of letting people know the correct time. One section favoured a time gun, and the other section advocated the control of the clocks by electricity. A time gun is already in existence, but the Harbour Trust at their last meeting decided by a big majority to discontinue their contribution of £50 towards it, so that probably the equivalent will be spent on electricity. At the Gas Committee meeting, Mr. Tittensor, the electrical engineer, formally submitted a recommendation that the present area of the system be extended so as to include a radius of between three and four square miles Under the existing state of things a radius of only about three-quarters of a square mile is scheduled. Mr. Tittensor was instructed to draw up a report showing the capital expenditure required for the proposed extension, the committee reserving their decision on the whole matter until that is done. Consideration was also given to the subject of the extension of the lighting of High-street and other thoroughfares by electricity. To effect an improvement in the present system of lighting, Mr. Tittensor recommended that the present lanterns be done away with and the canopy carrier adopted. This change would cost £8. 10s. per lamp, or £34 in all for the High-street lamps. As to the price charged for current, the present system of charging was at the rate of 5d per unit, which was the same as that charged to ordinary consumers. No charge, however, was made for carbons, trimming, or maintenance. Last year the four lamps burned altogether 3,709 5 hours, costing £154. 11s. 3d , or at the rate of £38. 12s. 9¾d. per lamp per annum, being 2½d. per lamp per hour. In Edinburgh the charge was £18 per lamp per annum. As, however, half the lamps were switched off about midnight, the actual cost per annum was £24 for lamps burning all night, and £18 for lamps burning only part of the time. He would recommend that the standards be each fitted with two bracket arms carrying two 50-c.p. lamps, and that at half-past eleven o'clock or thereabout in the evening the arc lamps should be turned off and these lamps turned on. On these lines High-street could be supplied at £25 per lamp per annum. He would also submit an extended scheme for the lighting of the principal streets in the town on the same lines as those which had been adopted in Edinburgh. He proposed to erect 56 extra lamp-posts with bracket hangers and lamps, and the necessary mains and pipes. The supply for these lamps would be taken direct from the mains supplying the town, and would not entail any alterations or additions to the present plant at the generating station. He further suggested that the energy be supplied at the rate of £20 per lamp per annum, including trimming, but exclusive of interest and sinking fund. The cost would be: 56 lamp posts, hangers, and lamps erected complete, £30 each—£1 680; laying and supplying pipes for the cables, £175; cables and switching gear, £330—total, £2,185. The interest and sinking fund would amount to £110, and the running cost—that is, supplying current, trimming, etc.—at £20 per lamp per annum, or 3d. per unit including trimming, £1,200. The committee approved generally of this report, but reserved consideration as to details.

Walsall.—Colonel A. G. Durnford, R.E., commissioner for the Local Government Board, has held an enquiry as to a proposal by the Town Council to borrow £2,500 for the purposes of electric lighting. The Town Clerk (Mr. J. R. Cooper) said that the population of the town according to the last census was 71,789 and the rateable value was £161,785. The outstanding loans were £168,011 for sanitary purposes. The present application was to borrow £2,500, repayable in 25 years, the same as the former loan. The former loan was £19,000, which was sanctioned in October, 1894, and of that £19,000 the Corporation had actually expended £18,690 according to the statement which he put in. At the time the former loan was sanctioned the Corporation contemplated erecting works, and the commissioner would see from the statement how the money had been expended. At that time two Lancashire boilers were put in, and they gave sufficient power for driving the engines in connection with the works, but the demand had really exceeded the expectations of the committee, and consequently further extensions were absolutely necessary. He might say that when the works were started, there were 42 customers and the output was 45 amperes at 2,000 volts. There were now 67 customers, and the output had increased from 45 to 60 amperes at 2,000 volts, showing an increase of 30 per cent. Then he was glad to say that the income had proportionately increased. The units sold in August were 42 per cent. higher than the units sold in July, while the units sold in July and August were together 95 per cent. more than for the months of May and June. The works which the Corporation had carried out comprised generating works and three transforming stations, and they commenced to run on December 21. One of the transforming stations was also a storage station. The current was generated at the generating station at 1,870 volts, and that was reduced at the transforming stations to 105 volts. At present the output at the transforming stations was 340 amperes each, while the three transformers would take 20 amperes each on the high-tension side. The three together would therefore take the whole 60 amperes from the generator at the present time, and the maximum loads reached the 60 amperes. Therefore, having regard to the increased demand which would be made during the winter, it had become absolutely necessary for the Corporation to put down another transformer and also another boiler so that in case of an accident there would always be sufficient power at the generating station. The present two boilers were required to meet the present demand, and they wanted a third in case of a breakdown. The matter had received the very careful attention of the committee and the Corporation, and they had come to the conclusion that to meet the demand likely to arise there was no alternative to this. The commissioner knew that electric lighting was one of those works which required very careful feeling and attention, and they had not overdone their expenditure at present, but to keep pace with the demands of their customers they were bound to do this work before the winter. He might say that so important did the committee feel this to be that they had already placed the order for the new boiler. The present boilers were of the Lancashire type, but as the Babcock and Wilcox type was a more rapid raiser of steam one of that type had been adopted. He then laid before the commissioner a detailed account of how the present £2,500 was to be expended, giving separate estimates for boilers, transformer, works, switchboards, etc. Mr. Wyllie (the electrical engineer), in reply to the commissioner, said that what was to be done was a repetition of what already had been done, no change of system or other alteration being contemplated. There were 14 public lamps belonging to the Corporation, but the greater part of the demand was from private consumers. The lamps supplied varied from 8 c.p. to 200 c p., but the great majority were of the ordinary 16 c.p.

Plymouth.—A Local Government Board enquiry has been held by Colonel Luard, R E., into an application by the Corporation for sanction to borrow £46,000 for electric lighting works. The Town Clerk said the Corporation in the year 1894 obtained an order under the Electric Lighting Acts. Inasmuch as it was then said in some quarters that electric lighting was in its experimental stages, the Municipality decided to proceed cautiously, and see whether, commercially or scientifically, that was so. A committee was appointed to deal with the matter, and to make enquiries of all local authorities as to what had been done. It was found that so far as local authorities had established electric lighting works, and had conducted them sufficiently long to enable a fair judgment to be made, they were a commercial success. Dr. Fleming, an expert, was then consulted, and his report was favourable to the introduction of electric light into the town. Some members of the Corporation having visited and inspected some of the chief electric lighting stations in the country, Mr. Rider, of Bolton, was appointed borough electrical engineer. He presented an exhaustive report (already printed in these columns) and the present application was based on that report. It was proposed to spend £46,000 on the works, and to have the generating station on the shores of the Cattewater, so that either water-borne or railway-borne coal might be obtained. The Board of Trade had already approved of the scheme, subject to certain proposals which they had to make. The population of the existing borough was 90,000, the ratable value to the general district rate £334,046, and the amount of the sanitary loans outstanding £309,016. The order, however, had been made applicable to the extended borough. Mr. J. H. Rider, the electrical engineer, put in his report, mentioning that the scheme provided for public and private lighting and traction power. The proposed power of the generating station was independent of the exact form of electric light which might be adopted; whatever system was adopted the power would be suitable. The committee had reported favourably on the overhead wire system. Mr. Debnam said from enquiries he had made the low-tension stations were those which were the most profitable, and he asked whether it was not possible to adopt that system. Referring to the traction power, the Corporation were proposing to charge the Tramway Committee 3½d. per unit for the electric power. He thought such a charge was unnecessarily heavy, and likely to hamper the efforts of the Tramway Committee to make that undertaking pay. In Portsmouth the Corporation had decided to sell to a private tramway company 1½d. per unit for electric power. The Inspector thought these points were outside his province. Mr. Rider, replying to Mr. Debnam, said with regard to the loss on the high-tension system as against the low-tension system, the provisional orders gave to corporations the power to supply the current over the whole of the borough in every case; but in no case had a low-pressure station been able to come up to its obligations to supply current over the whole of the borough. In every case the low-pressure station had its mains within a small area, never exceeding half a mile radius. That was the way in which the low-pressure system was made to pay. Plymouth Corporation, however, was bound to put down a system for the whole borough, and the high-tension system was the only one possible of adoption, unless low-pressure stations were established at various points. It was not in the total cost with the low-tension system so much as in the low working costs per unit that money was saved. Plymouth proposed to supply the current all day and all night, and in that way would be able to keep shifts

Digitized by Google

of workmen continuously employed. Mr. Debnam wished it to be made clear that he was not opposed to electric lighting. Mr. J. Willoughby said, as chairman of the Electric Lighting Committee, and as one who visited Brighton and other places, he was convinced, not only of the advisability of the scheme proposed, but of the fact that Plymouth was benefiting greatly by the experience of other towns. There was no opposition to the application, and the Town Clerk asked for a period of 50 years for the land, 30 years for the buildings, and the longest possible period for the rest of the works.

PROVISIONAL PATENTS, 1896.

SEPTEMBER 28.

21449. **Improvements in apparatus for measuring and recording electric currents.** Hermann Aron, 6, Lord-street, Liverpool.

SEPTEMBER 29.

21487. **Improvements in or connected with coin-freed or actuated electricity meters.** George Ellis and George Hinde Nisbett, 15, Water-street, Liverpool.

21488. **Improvements in or connected with coin-freed or actuated electricity meters.** George Hinde Nisbett, 15, Water-street, Liverpool.

21509. **An improved electrolyser or electrolytic apparatus** John Gustaf Adolf Rhodin, 17, St. Ann's-square, Manchester.

21527. **Improved door or sash bolt for use in connection with electric circuits.** John Joseph Wilson, 73, St Stephen's-road, Upton Park, London.

21539. **Improvements in or relating to telephones.** Alfred Julius Boult, 111, Hatton-garden, London (George Milton Bair and Calvin Westley Ream, United States)

21559. **Improvements in dynamo-electric machines.** The British Thomson-Houston Company, Limited, 70 Chancery-lane, London. (Charles P. Steinmetz, United States) (Complete specification.)

21560 **Improvements in tandem-parallel controllers for induction motors.** The British Thomson-Houston Company, Limited, 70, Chancery lane, London. (William B Potter and Frank E. Case, United States.) (Complete specification.)

21561. **Improvements in the means of supplying current to electrically-propelled railroad vehicles.** Frederic Joseph Warden Stevens, 70, Chancery-lane, London.

21583. **Improvements in or relating to electrical signalling apparatus.** John Groves Hamerton, 111, Hatton-garden, London.

21591. **Improvements in or connected with electric circuits for telephonic communication** Franz Rumrich Joseph Juraske and Hermann Brockett, 40, Chancery-lane, London. (Complete specification.)

SEPTEMBER 30.

21617. **Improvements in electric heating devices.** William Edwin Heys, 70, Market street, Manchester. (D Chedville, France)

21632. **Improvements in electric light fittings.** Edward Wynne Donovan, Broughton Bridge Ironworks, St Simon-street, Salford (Complete specification.)

21668. **Centrifugal contact apparatus for effecting the connection of the armature windings of rotary phase electromotors on the attainment of a certain speed.** Siemens Bros. and Co, Limited, 28, Southampton-buildings Chancery-lane, London. (Siemens and Halske, Germany.)

21684. **Improvements in joints for electric light fittings.** John Webb Singer, Walter Herbert Singer, and Edgar Ratcliffe Singer, 40, Chancery lane, London.

21688. **Improved means of applying electricity to the human body.** William Phillips Thompson, 6, Lord-street, Liverpool. (Karl Zdrahal and Josef Minárik Austria)

OCTOBER 1.

21749. **Improvements in active material for secondary battery plates.** The Sussmann Electric Miners' Lamp Company, Limited, and Sigmund Adolf Rosenthal, 77, Chancery-lane, London.

OCTOBER 2.

21809. **Improvements in electrical burglar-alarms.** John Herbert Bower, Bank-buildings, George-street, Sheffield.

21822. **Improvements in leading in wires of electric glow lamps.** George Davis, 38, Margravine gardens, West Kensington, London.

21826. **Improved grids for plates in secondary electrical batteries.** Thomas Froggatt, 59, Warham-street, Kennington Park, London.

21879. **An electric furnace or oven** C. A Timme, 4, South-street, Finsbury, London.

OCTOBER 3.

21930. **An improvement or improvements in the method of ensuring a quick break in electrical switches known as the "knife switch," "chopper" switch, or "hatchet" switch.** George Herbert Verity, Plume Works, Aston, Birmingham. (Complete specification.)

21956. **Improvements in or connected with electric accumulators.** Jules Julien, 6, Lord-street, Liverpool.

21960 **Improvements in electric bells.** Josef Mohr, 97, Newgate-street, London. (Complete specification.)

21972. **Improvements in dynamo-electric generators and motors.** Sidney George Brown, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1895.

18673 **Automatic speed regulator for electromotors.** Denayrouze.

18931. **Prepayment apparatus for attachment to gas, electricity, or other fluid meters.** Webber. (Date applied for under International Convention, April 16 1895.)

19245 **Dynamo-electric generators and motors.** Wood.

19734 **Means or apparatus for electrically igniting and governing petroleum and other like motors.** De Dion and Bouton.

19745. **Manufacture of plates for electric accumulators or secondary batteries.** Körner.

21283. **Electro-depositing of metals.** Elmore (Elmore.)

21830. **Electrical apparatus for firing fuzes for mines and other purposes.** Siemens Bros. and Co., Limited. (Siemens and Halske)

22586 **Single-phase alternate-current motors.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

1896.

3712. **Electric accumulators.** Mouterde, Chavant, and George.

5274. **Apparatus for the electro-deposition of metals.** Smith, Smith, Smith, Smith, and Deakin.

12895. **Electric elevators.** Smith.

16168. **Electric insulators.** Smock.

16726. **Electrodes for secondary batteries.** Schneider.

17123. **Insulating joints for metal or armoured conduit-tubes, more especially suitable for electrical conductors.** Lake. (Greenfield).

17124 **Conduits, more especially suitable for electrical conductors.** Lake. (Greenfield.)

17180 **Combined typewriters and electro-telegraphic transmitters.** Wise (World Flash Company.)

NOTES.

French Transatlantic Cable.—Three steamers belonging to the French Cable Company are now at Halifax preparing to lay the cable between France and the French colonies in America.

New Spanish Cables.—The *Gaceta* of Spain recently published a Royal decree announcing the intention to construct and establish three submarine cables to unite the islands of Luzón, Panay, and Negros y Cebú, in the Philippine Archipelago.

North-East Coast Institution of Engineers and Shipbuilders.—The second general meeting of the session of this association will be held in the lecture-hall of the Subscription Literary Society, Fawcett-street, Sunderland, on Wednesday, November 11, at 7.40 p.m.

The Pacific Cable.—It is understood that Mr. Laurier, the responsible head of the Canadian Government, intends to pay a visit to this country, in the course of which business questions attaching to the construction of the Pacific cable and the fast Atlantic service can no doubt be profitably discussed. The prorogation of the Dominion Parliament sets him free, and it is probable that the date of his arrival here will not be long postponed.

Leeds Mechanics' Institute.—"The New Photography" was the subject of an interesting lecture delivered on Wednesday evening before the members of the Leeds Mechanics' Institution and Literary Society in the Albert Hall. The lecturer was Mr. Richard Kerr, who explained the nature of the discoveries of Röntgen and Prof. Crookes, and showed electric sparks passing through various substances. He took a radiograph of the hand of the chairman, Mr. Arnott, which was passed round amongst the audience.

The Value of Electrical Engineers.—A farewell dinner party was given a short time ago in honour of a gentleman who was leaving London to take up a rather good position in France, and one of the guests in delivering a congratulatory oration remarked that it had been said on good authority that a labourer was worthy of his hire. The difficulty which faced electrical engineers as a rule was to find a hire worthy of the labourer, and they could congratulate their friend on having so successfully solved the question.

Newspaper Enterprise.—The *Glasgow Herald* have engaged a special correspondent in America to describe the chief systems of mechanical traction in use in that country, which will be read with more than ordinary interest by the citizens of Glasgow in view of the vexed state of the tramway question in that city at the present time. These articles may have a good deal of influence on the new Council, but if no steps are taken very soon, the whole matter may be postponed indefinitely. The first of these special articles appeared on October 10, and they are running daily.

The Corrosion of Aluminium.—The *Journal* of the Chemical Society summarises the results of the experiments of Mr. E. Donath on this subject. He found that hard aluminium foil is not attacked by boiled water, which is free from air, whereas ordinary water acts on it appreciably. Calcium sulphate in solution has no action on the foil, but solutions of chlorides, and especially of nitrates, dissolve it readily. Again, the author found that fats, fatty acids, and fused anhydrous phenol are all without action, but that a 10 per cent. boiling solution of phenol forms yellow spots, and caused part of the aluminium to enter the solution. He attributes this, however, more to the action of the air than to that of the phenol.

Illuminated Storm Waves.—The recent storms all round the south coast have caused considerable damage to sea-fronts. The waves dashing against the sea-walls and promenades are, however, always an attraction to visitors. The arc lamps now generally used to light the promenades add much to the beauty of these displays of wasted energy at night time. The illuminated effect as the waves roll and then break over the arc lamps can be compared favourably with many illuminated fountain displays. They are not so safe to watch, but the danger of a ducking give additional attraction to the scene.

The Telegraph in North Borneo.—Reuter's agent at Sandakan (North Borneo), writing under date of August 14, says: "I have just returned from the Labuk River, where all trade is at a standstill owing to Mat Saleh and his followers being in the district. The telegraph line across this country, which was put up from both ends, has now been joined, but owing to a breakdown somewhere near Sandakan no message has been sent through as yet. High winds have prevailed here for some time past, and as the track through which the line runs is not a wide one, falling trees are doubtless the cause of the break."

War to the Housebreakers.—M. Defert, secretary of the Commissariat of Police of the Saint-Avaye Quarter in Paris, has carried out an interesting experiment in the Fouillard Brewery, rue Montmartre. The system, of which M. Seguy, professor of physics at the School of Pharmacy, has given a demonstration, consists of an electric apparatus placed in the door-porter's room and a special lock fitted with a transmission plate, the whole connected with electric wires. If an instrument other than the special key is introduced into the lock, bells are put in motion and continue ringing. The porter thus has time to catch the invader before he has been able to proceed very far. The French paper, *L'Electricien*, adds a strong touch of dramatic realism to its description of the utility of this invention when it adds: "If this system had been applied to the War Office, the treacherous Dreyfus would not have been able to steal the documents in the desks of his colleagues after they had departed."

Small Portable Lamps.—The portable lamp supplied from a primary battery is a standard invention which may be relied on to appear at regular intervals. So we find that an enterprising firm at Calcutta are introducing "a novel and highly useful form of electric lamp which will be found to meet many requirements of residents in India, more especially those whose duties entail camp life or the living in roughly-got-up bungalows, or as engineers, surveyors, planters, etc. They will also be found of much use where a light is wanted for a short space of time, say 10 minutes or so, as in bed or bath rooms, store-rooms, verandahs, or in photographic dark-rooms, and similar situations." Unfortunately, this useful battery and lamp, which is also cheap and likely to last two to three years, have the qualification of giving light for a short space of time, "say 10 minutes or so." We do not know why engineers and surveyors in India should be satisfied with such short intervals of brilliant illumination, but similar novel and highly useful inventions in this country have failed from this cause.

The New Amazon Cable.—It is refreshing to come across a paper which is able to clothe its ideas in idyllic words, but it seems rather a pity that the transcendent genius which evolved the following poetic prose should be lost in the wilds of Brazil. What a vast scope there would be on the English technical journals! The paper in question remarks with regard to the inauguration of the new Amazon

Digitized by Google

cable, that "upon the realisation of this legitimately patriotic event the Amazon, as if wounded by the shock of great commotions, felt the red blood freezing in its arteries. Now its heart is palpitating ardently, and its broad, bronzed breast is absorbing with the air the light which is poured down in a golden profusion of auroras and sunbeams. And while the Giant, the haughty Lion of the North, slumbered on his couch in divine ecstasy, the universal god, the wise god Progress, poured into his breast a vein of light like unto a running rivulet, limpid and brilliant. And this mighty vein, filled with a liquid compounded of globules of sunrays, is called—Telegrapho!" Further remarks by the same author on the electric light and electric tramways will be received with interest.

Telephones in Japan.—According to the *Japan Weekly Mail*, the Japanese Government, with the consent of the Diet, is to appropriate a very large sum during the next seven years for the expansion of the telephone service. The work of construction is being now actively carried on at various important places, the present intention being to complete, by March, 1898, the contemplated expansion of the service in so far as concerns Tokyo, Osaka, Yokohama, and Kobe, as well as the new constructive work in Nagoya, Nagasaki, Shimonoseki, and so forth, and to establish connection between Tokyo and Kobe. According to estimates for the current fiscal year, the number of new subscribers in the four cities of Tokyo, Yokohama, Osaka, and Kobe, under the expanded system, will be 13,333, and of those in Kyoto and 35 other places where the service is to be newly established, there will be 6,800. Side by side with the erection of telephones in so many places, the authorities will also effect various junctions between places already furnished with telephones. For instance, a connection between Tokyo and Kobe will be established *viâ* Osaka, Kyoto, Yokkaichi, Kuwana, and Nagoya.

An Electrical Boat.—A submarine torpedo boat is now in process of construction in the yard of the Columbia Ironworks, at Baltimore. According to a contemporary, it is calculated that this boat will be able to maintain a speed of eight or nine knots per hour when submerged to a depth of 60ft. The motive power will consist of a boiler heated by petroleum, supplying steam to three triple-expansion engines capable of developing 1,800 h.p. A battery of accumulators and an electric generating plant will also form part of this boat's equipment. The operation of this vessel is briefly as follows: When it is desired to go under water the smoke-stack is housed and the top covered over. The engines will be kept at full speed, and by turning some rudders the craft may be submerged to any desired depth. The speed is afterwards to be maintained by the dynamos running as motors and supplied by the accumulators which were previously charged. It is calculated that the battery plant will enable the boat to maintain a speed of 12 knots per hour for short distances. Air for the crew will be stored in reservoirs, and the supply may be replenished by a pump connected to a rubber tube terminating in a float on the surface of the water.

Chinese Telegraphic Signals.—We gather from the *Electrical Review* of New York that the telegraphic system in China is much hampered by the difficulties of the Chinese language. The characters used by this venerable nation are not so few as might be desired. The dot-and-dash system answers perfectly with our alphabet of 26 letters, but does not rise to the occasion when some thousands of characters are required. In consequence, a code has been adopted for all messages. But as only about one-eighth of the words in the language appear in this code, the exact expression of a message cannot always be given. This, and the double conversion before the message can be despatched and delivered, hinders the advance of the telegraphic system, and we understand that it is also difficult to obtain men sufficiently educated to handle the messages. The net result is that, although the principal cities in China are interconnected, the revenue does not provide for the necessary expenditure. The rush for news and the use of the telegraph as an aid to business transactions has not yet developed in the land. It is strange that the original discovery of the use of a magnet in China should be followed by such a lack of appreciation of the telegraph.

Indian Import Duties on Dynamos.—The following extract from a recent Customs circular of the Government of India deals with the import duty on dynamos and accumulators. It would seem that some enterprising business man hoped to pass both dynamos and accumulators off as prime movers. The following reply shows that the attempt was not successful: "I am directed to acknowledge the receipt of your letter referring to the question of the liability to import duty of dynamos and accumulators, and I am to say that, as observed by the Board of Revenue, the decision of the matter turns upon the question whether a dynamo can be classed as a prime mover within the meaning of No. 14 of Schedule IV. of the Indian Tariff Act. A dynamo is a machine for the generation of electricity, which is ordinarily set in motion by the application to it of a steam-engine, or other prime mover; and it is therefore not a prime mover itself. An accumulator is still more remote than the dynamo from the source of motion, and therefore is also excluded from the definition of prime mover. I am accordingly to state that dynamos and accumulators do not come within the exemption accorded to prime movers; and are chargeable with duty unless they form part of machinery intended for the special purposes mentioned under Article 14."

The Temperature of the Sun.—We gather from *Cosmos* the following interesting experiment by Prof. Ceraski, carried out at the Moscow Observatory. He had the use of a large mirror constructed by Messrs. Gettliffe and Simon, of Paris. This mirror was remarkable for the accuracy of its construction. It was silvered at the back, and had a focal length of about 39in. The thickness of the glass was varied to correct for spherical aberration, and a high degree of concentration could be obtained with it. The professor tried the old method of measuring the temperature at the focus when the mirror was exposed to direct sunlight, and found it to be about 3,500deg. C. This experiment only proves that the temperature of the sun is higher than this. The experimenter then tried a similar experiment using an arc lamp in the place of the sun, and with conditions as alike as possible. The intensity of the luminous source was then known to be very nearly 3,500deg., but the temperature at the focus was found to be only 100deg. to 105deg. C. The professor proceeds to argue that as the temperature of the source in this case was incomparably greater than that at the focus, so the temperature of the sun must be very much higher than 3,500deg. C. He also thinks that similar experiments may enable a true estimate of the temperature of the sun to be obtained.

Street-Car Litigation.—The *Western Electrician* comments on two recent cases of importance, in which the rights and responsibilities of street railway companies have been involved. The decision of Justice Patterson that a passenger standing on the platform of a street car did not forfeit his right to damages in case of an accident created considerable commotion in street railway circles, although it has not as yet resulted in an order to conductors to keep the car platforms clear. The Supreme Court has also given

Digitized by Google

the following opinion as to the right of way in the case of cars and vehicles along the line of the street railway: "It is true that railway trains have the right of way, and if travellers in the highway know that the trains are approaching it is their duty to keep off the track. No such rule is applicable to the street railways and teams travelling in the streets of a city. The teams have a right to cross the tracks although cars are known to be approaching, otherwise teams would rarely be able to cross the tracks of street railways. Especially would this be true in Broadway, where cars are at all times in view and known to be approaching the point where teams are to cross." The Court adds that care is to be exercised by both motormen and drivers to avoid collision, and that whether there is negligence on the part of either is a question to be determined by the jury on the facts of each case.

Short Competitive Papers.—The secretary of the Gloucestershire Engineering Society, in his annual report, which was read at the meeting last week, says: "The council have spent a large amount of time and exercised very careful consideration in the preparing and arranging of a syllabus for short papers to be furnished in competition for prizes, and notices have been sent to the members inviting their co-operation in the matter; but I have with great regret and disappointment to state that no member has made any response to the invitation. This a matter which seriously affects the interests of the society, and in view of the fact that such a large number of artisans and mechanics (over 100) are members such a response might very reasonably have been expected. I sincerely hope that in the coming session each of the members will be able to furnish a paper, to last from five to ten minutes, and by such means greatly enlarge the interest of the meetings." The society includes within its scope of operations practically every branch of engineering, electrical and otherwise, even down to horseless carriages; and after this intimation by the secretary there ought to be no difficulty in securing a good supply of these competitive papers, which in themselves would be of great utility, besides enhancing the interest of the meetings.

Aluminium in Shipbuilding.—Colonel Henry F. Swan, in his presidential address at the meeting of the North-East Coast Institution of Engineers and Shipbuilders at Newcastle, said: "The great craving for excessive speeds, involving the lightest possible structures, especially in torpedo-boats, has led to the use of aluminium in some cases, but although this metal possesses many important qualities, and has been used with a certain amount of success, it cannot so far be reckoned as an important factor for general shipbuilding purposes. Concurrently with the great increase in the tonnage of individual vessels, and the size and weight of plates, beams, and angles, used in their construction, so has it become imperative to devise and adopt enlarged and improved appliances for handling them; it has therefore been necessary, not only to discard the machines of former days and replace them by others of a much heavier type, but also to provide mechanical means for lifting, and this is being done largely by cranes, worked both by steam and hydraulic power, as well as by electricity. An important example of the latter application may be seen in the yard of Messrs. C. S. Swan and Hunter, who have constructed large building sheds, carrying overhead electric cranes, thereby greatly facilitating the handling of the component parts of a vessel and depositing them in their required place in her structure."

Institution of Mining Engineers.—At the annual meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers, the president (Mr. R. S. Williamson) in his presidential address said that the day was not far distant when the use of naked lights underground would be prohibited by law, and electricity would no doubt form an important factor in lighting. Then all safety lamps should indicate the presence of firedamp and stythe. No doubt explosives were too largely used, more particularly in seams where a large percentage of round coal was not a necessity. He considered that the use of explosives should be subject to the most stringent rules, and, if gas was known to exist, should not under any pretence be used. The standing charges connected with coalmines were so great that any improvement calculated to reduce the cost of working was eagerly looked for. In his opinion, if mining associations and institutions would give good and substantial prizes for labour-saving appliances for use in mines, improvements would be made and the cost of working reduced. He was convinced that if they were to hold their own with their Continental competitors they would be compelled to give the question more attention. Foreign competition was viewed with contempt by some people, but unless they kept up to the times as far as economical working was concerned the competition would succeed sooner or later.

Electricity v. Gas.—In few, if any, towns in England has the fight between these two rivals been more keen than at Hastings. The gas interests have been actively upheld by the able engineer of the gas company, who does not hesitate to put his name to the statement that gas at 3s. per thousand can only be equalled for cost of light by electricity at 3d. per unit. Since the new system with alternate-current machinery has been introduced the electric light has persistently gained favour, in spite of the above prophecy. We have just received the latest pamphlet on the electric light side, and find that the resident electrical engineer is well able to keep up the fight. The pamphlet contains an excellent testimonial from a supplier using 150 lamps to replace 150 gas lights. He states "that the cost of lighting his premises during the first six months of 1896 with the new illuminant has been less than with the gas only in 1895 over the same period, and this in spite of having to pay for meters for both means of lighting this year, which represents an addition of 7s. 6d. to the cost. This is such a satisfactory result, and so different to what he was advised on all hands would be the case, that he felt bound to inform the engineer of it, as a testimony to the value of his own advice as to the distribution and placing of the lights throughout the buildings, and as to the candle power of the lamps to be used." This plain statement of fact will need some explanation when the gas engineer sends out his counter-blast.

Metallic Bobbins for Field Coils.—The *Electrical World* in a recent number summarises very clearly the advantages and disadvantages of the use of metallic bobbins for field coils. Apart from the better mechanical support which a metallic field bobbin affords the coil wound upon it, there is an important electrical advantage which may to a certain extent be obtained, but one which, however, is partially offset by a magnetic disadvantage. The metallic bobbin forms a closed secondary, which, in case the field circuit is broken, prevents an abnormal rise of voltage and a tendency to impair the insulation of the winding. This secondary action, however, makes that of the field magnet slower, and prevents it from responding to frequent and excessive changes in load, a condition which is very desirable but incompatible with the former. Quickness of action is sought by laminating the pole-pieces, while a slow action is to some extent restored by surrounding them with iron sheaths. Laminated pole-pieces are of unquestioned value in this respect, and the alacrity with which they allow of rapid fluctuations in the magnetic induction should not

Digitized by Google

be counteracted too strongly by the use of heavy metallic spools. The electrical conductivity of the latter therefore becomes a matter worthy of serious consideration. It should be large enough to allow of only comparatively small currents to flow resulting from sudden and excessive changes of magnetism, which will be sufficient to protect the winding at such times. The latest type of field bobbin in America is made of riveted sheet iron, and the heads are of cast brass provided with many perforations. While thus obtaining economy in material and ease of construction, it is probable that some designers have so increased the electrical resistance of their field bobbins as to secure an important advantage of which they were not aware. The sheet-iron bobbins with wooden checks, so largely used by English designers, have practically the same advantage. Where laminated pole-pieces are not used, of course these considerations do not enter.

A National Physical Laboratory.—The committee which was appointed a few years back by the British Association to consider the question of the establishment of a national physical laboratory have reported strongly in favour of the suggestion. The committee was a very able and representative one, and in their report they remark that if England is to keep pace with other countries in scientific progress, it is essential that such an institution should be provided, and this can scarcely be maintained continuously on an adequate scale except as a national laboratory supported mainly by Government. Its functions should be the observations of natural phenomena, the testing and verification of instruments for physical investigation, and the preservation of standards of reference (an extension of certain branches of work now performed by the Kew Observatory), and the systematic accurate determination of physical constants and of numerical data which may be useful either for scientific or industrial purposes. The committee suggest to those whose business it may be hereafter to approach the Government that some such sum as £20,000 or £25,000 would serve to erect a building sufficient for all immediate necessities, and that posterity may be left to increase it as need arises. A sum of £5,000 would provide a fair amount of initial instrumental equipment of a permanent kind, and the rest should be met out of an annual grant. They propose that the head of this national laboratory should receive £1,200 a year, and they estimate that the additional assistance required would raise the sum expended on salaries to a total of £2,500 a year. The maintenance expenses and the apparatus fund would be adequately covered by another equal sum, much of which could be derived from fees, so that they estimate altogether that a supplementary annual grant of £3,000 per annum, and an initial expenditure of £30,000 for buildings and equipment, would do all that is essential to carry out the scheme in a wise and worthy manner.

Telephonic Disturbances. — The International Tramway Union recently addressed a number of questions to the various engineers in charge of electric tramways to ascertain, if possible, the best means of preventing the traction current from disturbing telegraphic and telephonic circuits. At the recent meeting of this society Mr. Paul Van Vloten, of Brussels, made a report on this subject. He classes the possible disturbances under three heads—*i.e.*, those due to actual contacts between the circuits; those due to leakage current; and, lastly, those due to induction effects. He also considered that the preventives of the effects could be subdivided as to whether they tend to prevent the disturbance in the tramway conductors, or to prevent these disturbances from upsetting the telegraphs. As to the currents in the tramway conductors, their voltage and intensity cannot be changed, but means may be adopted to diminish fluctuation. Still, as the author points out in his report, the fluctuations due to stopping and starting of the cars are comparatively slow ones, and do not have much effect on the telephones. The more rapid oscillations always found in the power circuits are due to the commutator of the dynamo. The passage of successive commutator strips under the brushes and the momentary short-circuiting of a certain coil produced a regular and rapid fluctuation in the current supplied. This cause is most important, and the notes due to these vibrations can generally be identified. Another cause is the continual variation in the resistance of the circuit due to the contact resistance between the wheels and the rails and between the trolley and the trolley wire varying. The author then proceeds to review the replies sent in to the society on this matter, and concludes as follows: To reduce the telephonic disturbances it is advisable to employ commutators having a large number of sections, and to get as good a contact as possible between the wheels and the rails. The collecting gear also should preserve a good contact, and all vibrations of the car or permanent way avoided as much as possible. The evidence in the various replies sent in seem to show that a rubbing collector is better than a revolving trolley wheel.

Return Conductors.—Mr. F. O. Rusling, the superintendent of the Buffalo Railway Company, has read a most interesting paper before the New York State Railway Convention on the use of old rails as underground conductors. In the Buffalo district trouble had occurred due to electrolysis. The water and gas pipes had suffered considerably, and at the two worst places these pipes were found to be from three to five volts positive to the adjacent rails. These two points were respectively about 1,500ft. and 1,800ft. away from the power-house. An expert called in calculated that some £1,600 worth of copper would be required as return conductors to remedy the fault. It then occurred to Mr. Rusling that some disused steel rails might be employed, and with the expert's concurrence the following construction was adopted for the shorter length. Four rails were used in parallel, they were flat, centre bearing rails, originally weighing 56lb. to the yard, but were worn down to 50lb. or less; they were high in carbon, hard and brittle. The rails were bolted together in pairs back to back and arranged so that the end of one rail was at the centre of its mate. The bonding was effected by scraping contact spots with a file near the end of each rail and amalgamating them with the Edison solid alloy. A steel washer ¼in. thick, 1⅜in. inside diameter and 4in. outside, was dipped into hot insulating compound and placed against one rail so as to enclose the contact spot. The hole in the washer was then filled with the Edison-Brown plastic alloy, enclosing an amalgamated steel spiral spring. The upper rail was then bolted on and the completed conductor lowered to the bottom of the trough, resting on one edge so that gravity would maintain the contacts. With this arrangement two of the bonds on any one rail would have to give way before the circuit could be broken; each bond was made sufficient to transit 1,500 amperes. When the second set of rails was lowered into place, the trough was filled with a hot insulating compound and a cover nailed down. This four-rail conduit was connected up and carried at heavy load 1,100 amperes 1,500ft. with a loss of but four volts. To produce the same effect with copper at 6d. per pound an expenditure of £590 would have to be incurred, while the scrap value of the old rails was computed to be only £80. This first

Digitized by Google

return was found so satisfactory that one for the longer distance was put in hand. In this about 3,000 amperes had to be provided for, but 14 rails in parallel were employed. The author attributed the success to the bond used, and would not advise the employment of copper bonds for buried conductors.

Electricity in France.—Electricity as a motive power is becoming very generally recognised now on the Continent. Fresh companies and fresh schemes are continually cropping up, and we give details below of some of the latest projects. The French Thomson-Houston Company are about to commence the installation works of the electric tramways for the town of Alger. The generating works will be erected at the Pâté de Mustapha, and the machinery, in three groups, will have a capacity of 350 h.p. The energy will be furnished by three dynamos of 200 kilowatts each. The carriages will be supplied with two motors, one for each axle, and will accommodate 42 passengers. They will be lighted with five lamps of 16 c.p. The whole line is to be lighted by electricity at night. The fares will remain the same, and everything that the Algérois can desire is being done to give a prompt solution to the question. The company is bound to commence the works 45 days after receipt of the necessary authority, and it is estimated that five months at the most will be sufficient to carry it to completion. A presidential decree of September 11 last declared of public utility the establishment of an electric tramway in the department of the Rhône for the conveyance of passengers between the boulevard of the Croix-Russe, at Lyon, and the suburb of Caluire, to the right of the Rue Vignoles, near the Place de l'Eglise. The same treaty approves the agreement made between the Prefect of the Rhône and Mr. Alexandre Durand, in which the latter agreed to construct and exploit the line at his own risks, without a subsidy or guarantee of interest. After a considerable delay work has been commenced on the electric tramway at Besançon. The electric tramway is likely to be installed soon at Chalons-sur-Marne. The building of the works is commenced, and in a week or two the boilers and motors will be fixed. Steps are being taken to establish an electric tramway between the town of Hyères and the neighbouring municipality of Toulon. The Municipal Council of Marseilles is busy discussing this question of traction, arising from the proposal of the Compagnie Générale Française des Tramways to substitute electricity for animal power. The overhead wire is proposed, and the principal objection on the part of certain members of the Council seemed to be that the supporting columns might impede the traffic. The engineer to the company (Mr. Doux) allayed all apprehensions on that score, and the question will be again gone into. At Nantes, too, there seems to be great competition. Besides the works already in course of execution for an electric tramway, three companies have placed before the Municipal Council proposals for new lines. A somewhat natural sequence has followed on the establishment of the electric light at Oran; it has now been decided to lay down a network of tramways. At a meeting of the General Council of Drôme, Mr. Noyer proposed the construction of an electric railway between Taulignân and Chamaret. After a long discussion the proposition was referred to the Finance Committee. This concludes the list as far as France is concerned at present, but in many other towns the question is being agitated. At Grenoble, for instance, in the department of the Isère, the preliminary formalities have been concluded of a line which will run out into the suburbs, and which will have some great difficulties in the way of gradient to overcome. Grenoble is, so to speak, in the centre of a very hotbed of electricity. The unlimited and stupendous water power obtainable at innumerable points in the surrounding mountains makes electricity produceable at a cheap rate, and consequently the electrical engineer's trade is a flourishing one there. Some of the smallest villages even have their public installations, and the use of the light is being very rapidly extended in the mountainous districts.

Visible Electric Waves.—Mr. B. E. Moore communicates to the current number of the *Physical Review* an interesting account of some of his experiences. We believe that a somewhat similar effect was noted by Dr. Lodge soon after Hertz's discovery was published. Mr. Moore used a quadruple-plate Toepler-Holtz machine as his generator, and connected a three-quart Leyden jar to each pole. The other coatings of the jars were connected respectively to two wires about 8in. apart and 23ft. long. At the end of these was connected a Crookes tube. As is well known, with the apparatus arranged as above described and a powerful induction coil substituted for the Toepler-Holtz machine, one can locate the nodes of the electric waves by simply sliding a rider along the wires. As was rather expected, the rider placed at any point whatever along the wire obliterated the discharge through the Crookes tube. The room was darkened, with the hope that a slight glow could be obtained when the rider rested upon the node points. This led to an unexpected result. When the discharge occurred, the wires were aglow with the electric waves. (There was no rider across the wires.) The observer working the machine sees, at every discharge of the primary, the wires momentarily illuminated. But all parts of the wire are not illuminated alike. At some points of the negative wire, the circle of illumination is little larger than the wire itself. Halfway between two such points the circle of illumination is often 1½in. in diameter. The whole presents the appearance of a solid sine wave—not unlike the appearance of circularly vibrating strings. Looking at these waves from the side instead of from the end, the phenomena are different. The nodes and crests are distinct as before, but the illumination no longer appears continuous. In a plane normal to the negative wire a fine illuminated rectilinear discharge in the form of rays or pencils occurs. These rays are often branched. They radiate from the wire as a centre, and form a circle about the same, often 1½in. in diameter at the crest of the wave. At a distance of 2½in. to 4in. on either side of the crest appears another such illuminated circle. These circles diminish in size as the node is approached. The circumferences of these circles form the solid sine curve. The positive discharge was entirely different. The crests and nodes upon the positive wire were only apparent to a close observer, and were not distinguishable at all until the room was well darkened and a wood screen so placed as to cut off the light radiated by the Crookes tube. The circles of illumination so apparent upon the negative wire were entirely absent. The illumination of the wire was continuous, and confined almost to the surface of the wire. The light emitted by the crest of the wave seemed only more intense than that emitted by the node. Only those who had some experience in photometric measurements could easily detect a difference. The waves along the negative wire can be made visible to an entire audience by cutting off the light of the Crookes tube. The eyes should be protected from the spark of the primary discharge. However, shielding the wire from the light of the discharge is detrimental. The author states that this method of showing electric waves is particularly serviceable for lecture purposes. A general audience can more highly appreciate it, as no process of inductive reasoning is involved. The waves stand out vividly, and are no abstractions.

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 375.)

73. The effect of inductance in an alternating-current circuit is a twofold one. It diminishes the current in the circuit by increasing the impedance, and it causes the current to lag behind the impressed E.M.F. as regards phase. This lag of the current behind the impressed E.M.F. gives rise to many remarkable effects. Some of these, which have been more particularly studied by Prof. Elihu Thomson, we shall now proceed to explain. The interest which attaches to these phenomena is not a purely theoretical one, for the principles underlying them have received a practical application in the construction of a number of alternate-current instruments.

74. Consider a conducting mass placed in a magnetic field, and let the field be made to undergo a change. During the time that the field is changing, E.M.F.'s are induced in the conducting mass, and give rise to currents in it. The direction of these currents is, by Lenz's law (Art. 24), such that they tend to oppose the change in the magnetic field which gives rise to them. Hence the conducting mass will tend to move (whether by a motion of translation, or by a motion of rotation) so as to prevent the change in the magnetic flux through it.

As an example, suppose that a short cylinder of metal L M is placed in the magnetic field shown in Fig. 55.

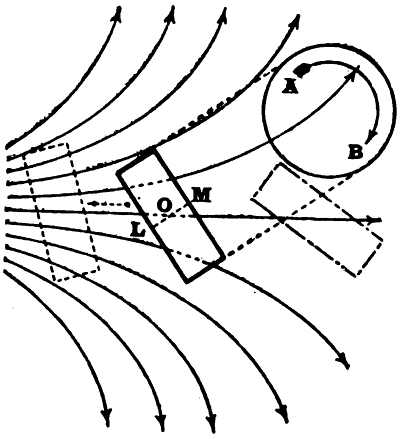

FIG. 55.

For the sake of simplicity, we shall suppose that the cylinder is suspended by means of a very long silk fibre attached to the point O. This will allow the cylinder considerable freedom of motion. Let the magnetic field be now weakened. The currents induced in the cylinder will have the direction indicated by the arrow A B when looked at from the side L of the cylinder. These currents will tend to move the cylinder so as to maintain the magnetic flux through it unaltered—*i.e.*, so as to produce by the motion an increase in the number of lines while the field is diminishing. Now, an increase in the number of lines passing through the cylinder may be brought about in two ways: (1) by a bodily movement of the cylinder into a stronger part of the field—hence the cylinder will tend to move bodily in the direction of the dotted arrow; (2) by a rotation of the cylinder about a vertical axis in such a direction that its plane faces tend to become perpendicular to the direction of the field. In other words, the cylinder will be acted on by a force and a couple; the first will produce a motion of translation, the second a motion of rotation, and the cylinder will be deflected and rotated into some such position as that shown dotted in the figure.

If we suppose that the field is increased instead of being diminished, then all the actions we have just considered will be reversed, and the cylinder will tend to swing into the position shown chain-dotted in the figure.

75. Let us next suppose that the magnetic field in which the cylinder is placed is made to alternate between two equal and opposite values. This effect might be produced by the pole of an alternate-current electromagnet held near the cylinder. For the sake of simplicity, we shall suppose that the magnetic flux through the cylinder varies according to the simple harmonic law. Let the curve A B C D E (Fig. 56) represent the variations in the intensity of the magnetic field. The rate of change of the magnetic field will be represented by another sine curve (shown dotted in Fig. 56) which is in quadrature with the first curve (Art. 22). Now since the E.M.F. induced in any circuit inside the cylinder is measured by the rate of change of the magnetic flux through it (Art. 23), it follows that all such E.M.F.'s will be represented by curves such as the dotted curve in the upper part of Fig. 56. Again, if the circuits along which the currents flow inside the cylinder were devoid of inductance the currents in them would be in phase with their respective E.M.F.'s. Hence the currents would also be represented by curves such as the dotted curve in Fig. 56, being in quadrature with the field. The force or couple due to any one of these currents would at any instant be proportional to the product of current and field intensity at that instant. But the mean value of two sine functions which are in quadrature with each other is zero (Art. 61). Hence there would be no resultant action on the cylinder, the successive

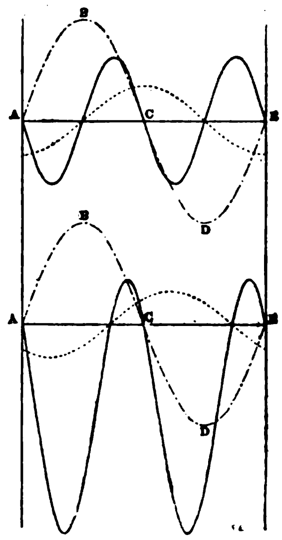

FIG. 56

impulses which it receives being represented by equal positive and negative half-waves, as shown by the full-line curve in the upper part of Fig. 56.

We know, however, that the circuits in which the induced currents flow in the cylinder have a certain amount of inductance. Owing to this fact, the currents, instead of being in phase with their respective E.M.F.'s, lag behind them. The dotted curve in the lower part of Fig. 56 is supposed to represent one of the currents, and it will be noticed that this curve lags behind the dotted curve in the upper part of the figure. The result is that now the successive impulses received by the cylinder are no longer balanced; the negative impulses considerably exceed the positive ones, as shown by the full-line curve in the lower part of the figure. On the whole, therefore, the cylinder will experience a negative force and negative couple, and it will tend to take up permanently some such position as that shown chain-dotted in Fig. 55. In other words, there will be an apparent *repulsion* of the cylinder by the pole of the alternating electromagnet, and the cylinder will tend to turn round so as to make the magnetic flux through it a minimum.

76. Instead of dealing with a large conducting mass placed in a variable field, let us next suppose that we have a simple rectangular frame of wire, A B C D (Fig. 57), suspended as shown in a field which is uniform,* and which varies as time goes on according to the simple harmonic

* Based on a series of evening lectures delivered at the University College, Liverpool.

* *i.e.*, which has the same value from point to point of the space considered. *Uniform* refers to *space*, *constant* to *time*. A field may be *uniform* and yet not *constant*.

Digitized by Google

law. In accordance with the principles explained above, the frame will tend to move so as to reduce the magnetic flux through it to a minimum. Now since the field is uniform, a pure motion of translation would not reduce the magnetic flux through the circuit. The frame therefore simply tends to turn round so that its plane becomes parallel to the field. It experiences a couple due to the forces acting on the sides A B and D C. Let each of these forces be denoted by F, and let θ be the angle which the plane of the circuit makes with the direction of the field. We shall investigate for what value of the angle θ the couple becomes a maximum. Referring to the diagram

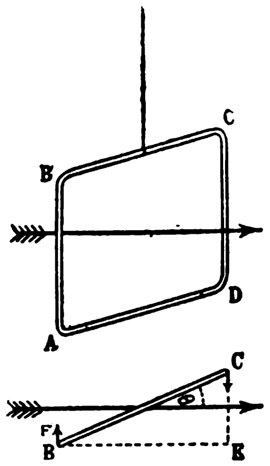

Fig. 57.

(Fig. 57), and denoting by c the couple acting on the frame, we have $c = F \times B\,E.$

Now F is, for a given field intensity, proportional to the current, and therefore to the E.M.F. induced in the frame; this E.M.F. is measured by the rate of change of the magnetic flux, and is therefore proportional to the maximum value of the flux. The latter, again, is proportional to E C; so that

$$c \propto E\,C \times B\,E$$

But $E\,C = B\,C \sin\theta$, and $B\,E = B\,C \cos\theta$ (Art. 6). Hence, since B C is a constant,

$$c \propto \sin\theta \times \cos\theta,$$

or, $$c \propto \sin 2\theta,$$

since by Art. 8, equation (8), $\sin 2\theta = 2 \sin\theta \cos\theta$. The greatest value of the couple will therefore be obtained by placing the frame in such a position that $\sin 2\theta$ has the greatest possible value. But the greatest value of the sine of an angle is 1; and the corresponding value of the angle is $\frac{\pi}{2}$ (a right angle). Hence θ must be made equal to 45deg. if the couple experienced by the frame is to be as great as possible.

77. A galvanometer for measuring very small alternating currents has been constructed by Dr. Fleming, in which

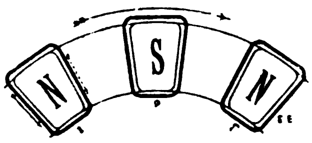

Fig. 58.

the above principles are made use of. It consists of a coil of wire, inside which is suspended a small disc of copper whose plane makes an angle of 45deg. with the axis of the coil. The couple acting on the disc is proportional to the product of the current induced in it into the field intensity. But the induced current is itself proportional to the field intensity. Hence the couple acting on the disc varies as the *square* of the field intensity—*i.e.*, as the square of the current through the galvanometer coil. If we suppose that the deflections of the disc are small, so that the couple remains practically unaltered by the displacement of the disc, then we see that the deflections of such a galvanometer are proportional to the *square of the current.*

A number of other instruments have been devised whose action depends on the principles explained above.

78. Before dismissing this subject, we shall consider the effect of phase difference between armature E.M.F. and current on the field of an alternator. Let, in Fig. 58, N S N denote the polar projections of an alternator, and let 1, 2, and 3 be three positions of an armature coil. The E.M.F. passes through its zero value when the coil occupies the positions shown. Between the positions 1 and 2 the direction of the E.M.F. is that shown by the full-line arrow; between 2 and 3, that shown by the dotted arrow. The positions of the coil indicated in the figure are those in which the armature current can most readily affect the field, since the coils in these positions are facing the polar projections. If the armature current is in phase with the E.M.F., then, on the whole, it exerts no strengthening or weakening effect on the field; for in the positions of the coils calculated to produce the greatest reaction on the field, the current passes through its zero value; and in other positions of the coils such weakening effects as are produced when a coil is approaching a pole are balanced by equal strengthening effects when the coil is receding from the pole.

Suppose, however, that the alternator is working on an inductive load, and that consequently the current lags behind the E.M.F. In this case, when the coil is in the position 1, there is a current flowing in it, whose direction is indicated by the dotted arrow. The coil will therefore exert a demagnetising effect in this position, and this effect will increase with the lag of the current. We thus see that a *lagging* current *weakens* the field of an alternator.

Again, let us suppose that the current is in advance of the E.M.F. as regards phase. Then the action will obviously be reversed, and hence a *leading* current *strengthens* the field of an alternator.

Corrigendum.—On page 342, Art. 62, line 6 from beginning of article, the sentence, "This storage of energy . . . and returned to the source of alternating E.M.F.," should read as follows: "The storage of energy *due to this component* goes on so long as the component is increasing; when it reaches its maximum value, the storage due to it ceases; and during the next quarter-wave, when it is decreasing, the energy stored up by it is discharged from the circuit, and returned to the source of alternating E.M.F."

(To be continued.)

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 400.)

In addition to the operations described, the placing of the signal lever in the "off" position breaks the connection of the locking electromagnet with the line wire to the advance cabin, and connects it with the special circuit and battery to the rail treadle (up-line instrument at "C," Fig. 75). Remembering that the apparatus locks the signal lever in the "off," as well as in the "position, on"

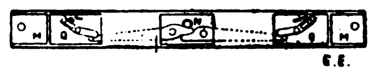

Fig. 73.

and that "locked" appears at the upper opening at this stage of the operations, it will be seen that it is impossible to release the armature, A, by a current from the advance cabin quite irrespective of the locking of the plunger at that place consequent upon its use to release the armature in the first instance. In addition to the apparatus described, the system includes a mercury contact rail treadle (Fig. 73), in which the contacts are made by the tilting of the vessels containing the mercury, consequent upon the depression of the rail acting through a plunger on the short ends of two levers to the longer arms of which the vessels containing

Digitized by Google

the mercury are connected. There is also an automatic arrangement for replacing the signal arm in the "on" position by the passage of the train over the treadle irrespective of the position of the lever operating the signal under normal conditions. The automatic signal replacer is shown by Fig. 74. The rod actuating the signal is attached directly to the upper part of the box containing the apparatus, and the slide bar, *f*, is worked by the lever

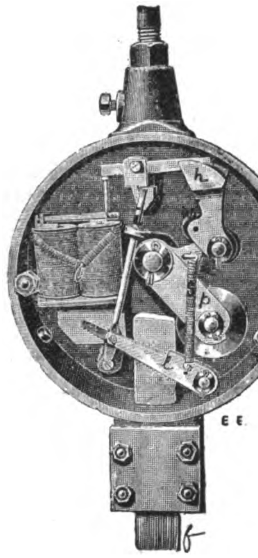

Fig. 74.

from the cabin. The normal position of the sloped upper end of *f* is under the lever *l*, in which case the slot on the upper surface of *l* engages with the slot on the lower surface of *p*, the latter being pulled into a vertical position by the spring, *s*. Under these conditions the box and the apparatus it contains work with the movement of the signal lever, the upward movement being transmitted from *f* through the levers, *l* and *p*, to the case and the rod working the arm, and the downward movement by the greater weight of the box and rod as compared with that of the signal arm outside the centre on which it turns. If the electromagnet is energised, the hammer, *h*, is released and falls

Consideration of the illustrations, and description of the functions of the various pieces of apparatus forming the system, will show that the objects aimed at in the design do not differ materially from those of other systems, but the arrangement of the apparatus is novel, and the electrical devices are of the simplest possible character. Fig. 75 is a diagram of the connections for a simple block section such as is shown by Fig. 9; but the block bell connections are omitted, as they differ in no way from those described in connection with the three-wire single-needle system, and are entirely independent of the block indicators and locking apparatus. The paths of the currents will be easily traced from Fig. 75, which is drawn to represent the positions of the apparatus on the assumption that a train is passing through the section from "B" to "C" on the up line. This train has been accepted by D as shown by the horizontal position of the semaphore arm of the up-line instrument working from D; and the change in the connections of the electromagnets shows that the starting signal at "C" is "off," whilst the position of the armature and the "locked" indication exhibited show that the signal lever is locked in the off position. The indication "Train on" at "C" shows that the plunger has been used to liberate "B's" signal, and is itself now locked. The position of "B's" electromagnet connections and the "locked" indication exhibited show that the train has passed over the treadle at "B," and that the signal lever has been placed in the "on" position; whilst the position of the switch, T, at "B" indicates that the train has not been cleared back to "A," or that "B" has undertaken shunting operations involving the fouling of the running line inside the starting signal. The switch, T, in the position shown at "B's" up-line instrument would embrace the plunger rod and prevent it being used inadvertently.

The novel arrangement of the battery used in operating the plunger is intended to minimise the chance of inconvenience being caused by failure of the battery or its connections. The batteries act in parallel when in use, and the connections to the battery terminals in the instrument are duplicated. Of course the chance of failure with two batteries, each capable of doing the work, is much less than with one battery alone. As shown in Fig. 75, however, failure of the battery earth would render both batteries inoperative, and it would therefore be necessary to carry

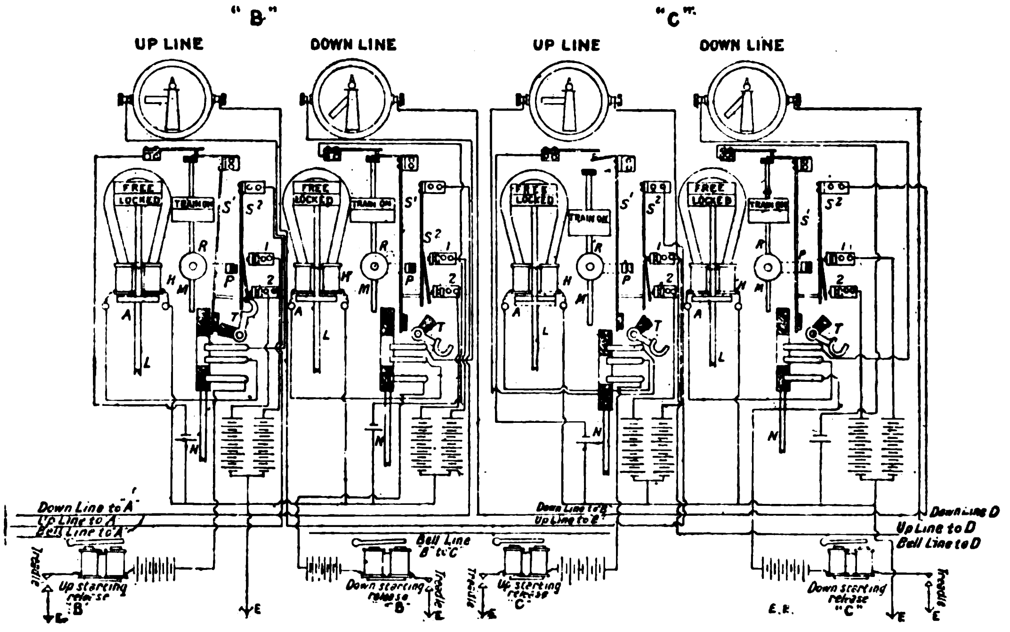

Fig. 75.—Sykes's Lock and Block.

upon the rod, *i*, and disconnecting the two slotted levers, *l* and *p*, allows the box to fall and place the arm at danger. The wheel, *w*, is pressed outwards by the sloping end of *f*, and causes *p* to turn on its centre. The Λ-shaped projection of *p* engages with the wheel, w_1, on *h*, and causes the latter to assume its original position. When the signal lever is placed in the "on" position, the slide, *f*, is lowered, and *l* engages with *p*. The apparatus is then ready for further use.

the duplication of connections to the fullest extent in order to secure all the advantages accruing from the use of duplicate batteries.

Fig. 75, as stated, represents the arrangements for working the simplest possible block section only. For junction working the arrangements have necessarily to be more complex. For such a junction as Fig. 11 represents releasing treadles are required for each of the *diverging* lines, and each treadle must be capable of working the

Digitized by Google

same instrument. For the lines *converging* at the junction the plunger used to liberate the signal at the rear cabin of any one of the converging sections is arranged to be free for use only when the points have been set for a train coming from that direction. This, of course, with the usual signal and points interlocking would mean the control of each plunger by the "home" signal for that section, and would ensure all other signals for lines converging there being at danger. Only one treadle would be required for trains coming from any of the converging lines. The arrangements for special cases like junction working will, however, depend greatly upon local conditions, and it is not possible to give more than the barest outline of the arrangements for such cases.

Circumstances will, however, sometimes arise in apparently simple cases which would seem to indicate the necessity for more elaborate arrangements than are shown by Fig. 75. Fig. 10 is a very simple block station, but if we assume the arrival of a train at that place with a bare time margin in front of a more important train, the necessity for shunting the first will arise. If the releasing treadle is placed at or in advance of the "advance" signal, and there is only one treadle, the train which is to be shunted will require to actuate the treadle—in which case it may actually be in the advance section—before the starting signal (which is assumed to have been lowered) can be replaced. If the starting signal has not been lowered, the signalman knowing the train will require shunting, then some further arrangement will be required to release the plunger in order to use it to enable the second train to advance when the first has been safely shunted. Further consideration of the same case would suggest the possibility, with only the arrangements described, of the shunted train being afterwards allowed to proceed to the "advance" signal, and of a second train being brought into its rear from the rear cabin, since the starting signal being "on" the plunger would not be *absolutely* locked. Of course, the case cited would be readily met by establishing control of the instrument with the siding points levers, or even control of the switch-handle, T, with the same lever, but the case is given simply to show that in apparently simple cases the arrangements for complete safety against the results of carelessness or neglect must be more elaborate than would seem necessary at first sight. Further consideration of the apparatus suggests the possibility of the starting signal being unlocked by contact of the block instrument line wire with another working wire on the same route, and this, in combination with other circumstances, not altogether unknown in railway work, might result in two trains being in the section on one line of rails together. This, of course, is by no means peculiar to the instrument just described, but is common to all classes of instrument in which the movements resulting in the release of locking apparatus or the setting of the indicators in their more important positions, are due to one person only. Of the various classes of instrument described in these articles, only two, Preece's and Winter's—two instruments which have much in common—take notice of the effect likely to be produced in this way. Whilst the danger of serious results from such causes is very much less now than a few years ago, owing to improved construction of lines and greater vigilance in maintaining them in an efficient condition, yet line contacts are not entirely things of the past, and, as has already been remarked, the history of railway accidents is full of instances of curious combinations of circumstances which would appear as most improbable of simultaneous occurrence. In this system, as in others of a similar kind, cancellation of a signal which has resulted in the preparation of the line for the passage of an approaching train can only be done by special means, which may or may not be immediately available for use by the signalman, and the use of which is an infringement of the automatic character of the apparatus. In some cases cancellation is directly prohibited, and the replacement of the apparatus in its normal position is made by the next train in that direction, it being worked through the section at "caution" in consequence of the defect in the apparatus. Probably such a regulation would do much to promote care in the despatch of signals asking for the clearance of apparatus for an approaching train, seeing that every lapse and the consequent delay would have to be fully explained.

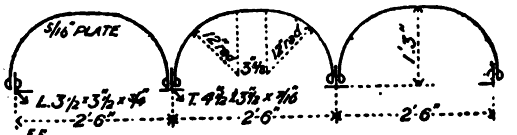
The system, like others, whilst providing for the automatic clearing of the section by the passage of the train itself, makes no provision for automatic notification of the *entrance* of the train into the section at either of the cabins controlling it. Yet, surely, if it is undesirable for the signalman at the receiving end of the section to trust entirely to his observation for guidance in clearing a section, it must be equally undesirable for him to trust to the signalman at the sending end for notification of the entrance of a train; and circumstances might easily arise where such independent notification would be of the utmost value to the signalman at the receiving end of the section in the event of an unauthorised train entering a section through the prevalence of fog or other similar cause.

(To be continued.)

LIVERPOOL OVERHEAD RAILWAY.*

BY S. B. COTTRELL, M.I.C.E., M.I.M.E., ENGINEER AND GENERAL MANAGER.

For many years before this railway was constructed, the want of proper facilities for conveying passengers to and from the docks was badly felt, the only direct means of conveyance being by means of omnibuses, which badly met the requirements. In 1852 a proposal was made to have a high-level railway from the Mersey forge to the Huskisson Dock—a length of about four miles—but nothing came of the proposal. About 17 years ago the Mersey Docks and Harbour Board felt that the question of better means of communication to the docks required to be seriously considered, and after careful investigation of the elevated system in New York, Mr. Lyster, M.I.C.E., prepared plans and estimates. In 1882 an Act was obtained by the Dock Board for the construction of the railway at an estimated cost of about £585,000, which was subsequently reduced to £466,000 for a system worked by electricity. In 1888 the power to construct the railway was taken over by the present Overhead Railway Company under the chairmanship of Sir Wm. B. Forwood, and the works, as designed by the engineers, Sir Douglas Fox and J. H. Greathead, Esq., MM.I.C.E., were commenced by the contractor (the late Mr. Willans) in 1889.



SECTION OF FLOORING

FIG. 1.

The railway extends the full length of the docks, and with the northern extension (opened in 1894) and the southern extension (under construction) will connect the suburbs of Seaforth and Waterloo with those of Princes and Sefton Parks. The construction decided on was wrought-iron girders, placed 22ft. centre to centre, at a normal span of 50ft., at a height of 16ft. above the roadway, supported on columns which are built of two steel channels and two plates. The columns are grouted into cast-iron shoes, which are held down by bolts to concrete foundations, the size of which varied according to the nature of the ground, the weight being distributed at one ton to the square foot. The bottoms of the columns are protected against injury from passing wagons by cast-iron bumpers. The longest span on the present railway is a bowstring span of 98ft. The main girders carry a light projecting parapet, and a curved plate is put on the flange to form a continuous footplate. Between the girders is fixed a continuous flooring made of arch plates 5-16in. in thickness, bent to a radius of 12in., with a foot surface 16in. wide on the top, riveted to intervening tee bars. The flooring is made watertight by means of asphalte channels between the arches, which are drained by outlets into longitudinal gutters which discharge into downspouts fixed on the columns. The keeping of the structure watertight was one of the obligations the company were under. The flooring (Fig. 1) combines great strength with lightness and a minimum of riveting, and at the same time is comparatively noiseless under traffic. The structure was so designed that the girders and flooring were put together and riveted, and then transported over the structure after it was completed (a few spans being

* Paper read before the British Association at Liverpool.

Digitized by Google

first erected in the ordinary way), and placed in position without interfering with the traffic underneath. For this a special form of erecting apparatus was provided, consisting of lattice girders supported on legs, the front pair of which travelled on the ground and hind pair travelled on the viaduct that was already built. On these lattice girders suitable cranes were erected, so that the completed span could be launched forward into position. As many as 12 spans, ranging from 50ft. to 70ft. each, were fixed in 5½ working days, representing 650ft. of finished viaduct.

At four different places along the line opening bridges had to be provided. At the Stanley Dock a hydraulic swingbridge is built to enable vessels to pass to that dock, which is the only dock on the east side of the railway. This bridge is a double-decked one, carrying the Overhead Railway on the high level and the dock traffic on the lower level. The low-level bridge is arranged with bascule leaves, so that barges and small craft can pass through without swinging the bridge. At three other points bascule bridges, worked by hydraulic power, are provided to permit the passage of boilers, etc., which are too high to go underneath the main girders. The permanent way, which is laid to a gauge of 4ft. 8½in., consists of flat-bottomed steel rails weighing 56lb. per yard, fixed on longitudinal sleepers, held down to the flooring by lugs riveted on to it and keyed in with oak keys. The rails are fixed to the longitudinal sleepers by spikes and fang bolts.

After careful consideration, electric traction was decided on, and trains were built consisting of two carriages, each 45ft. long, 8ft. 6in. wide, on two bogies 32ft. apart from centre pin to centre pin, with 2ft. 9in. wheels. Each carriage contains seating accommodation for 16 first-class and 41 second-class passengers. The carriages have side doors and passage from end to end. Each carriage is fitted with electric motor, and the train is controlled by a driver from either end; this avoids all shunting at the terminal stations, the driver simply changing from end to end. The armatures for the motors are series wound (on the Eickemeyer system), and built directly upon the axle. The tractive force of each motor at rim of wheel, 2ft. 9in. diameter, with 120 amperes, is about 1,790lb.—equal to about 107lb. per ton of train. The motors are started up first in series, and then switched into parallel through a resistance with each motor, which is cut out to increase the speed. The trains pick up the current from a conductor consisting of a steel bar, having an area of four square inches, supported on insulators carried on cross-timbers between the two running rails. The conductor is laid in 32ft. lengths connected with rigid copper fishplates with flexible joints every 96ft. The running rails which are used for return electrical circuit are, in addition to the fishplates, coupled together with a bent wrought-iron bar, and give a section of 22 square inches. Short trains, as described, run at frequent intervals, have proved up to the present time the best means of meeting the requirements. The trains are fitted with the Westinghouse automatic brake, supplied with compressed air at 80lb. pressure from reservoirs on trains, which are charged at the terminal stations; they also have an emergency hand-brake. A train fully load weighs 38 tons, of which the motor equipment is 6 tons 7cwt. The carriages are lighted by 32-c.p. incandescent lights, supplied from the main conductor.

The generating station was put as near the centre of the line as a site could be obtained, and the first equipment consisted of six double-flue Lancashire boilers, 30ft. long by 8ft. diameter, with a pressure of 120lb. The feed-water is circulated through Green economisers, and all steam-pipes are in duplicate. The engines are four in number, consisting of horizontal compound condensing engines, by Musgrave and Sons, of Bolton; the high-pressure cylinders being 15½in. and low-pressure 31in. diameter, fitted with Corliss valves, driven by trip gear acted on directly by the governor. Each engine develops 400 i.h.p. at 100 revolutions per minute, with 120lb. boiler pressure. The engines exhaust into surface condenser, the circulating air-pump for which is driven by a no-dead-centre vertical compound engine. The condensing plant is in duplicate. Each engine drives an Elwell-Parker dynamo, 500 amperes, 500 volts (of the double-limb type), with magnetic circuit above and below the armature, the poles being cut through horizontally along the centre to allow the top half to be lifted readily; they are shunt wound of drum type. The efficiency of the dynamos and engines is about 85 per cent. at full load. The current from the dynamos is controlled by a switchboard, which is equipped with magnetic cut-outs, which work automatically in case of a short-circuit, by which the current is conveyed to the centre conductor, and is picked up by collectors of cast iron, fixed underneath the trains. The stations on the original line, 13 in number, subsequently increased to 16, are lit by electricity from batteries in duplicate on a 50-volt circuit, which also supply the current for working the signals.

Signals.

The signals (Fig. 2) are automatic (Timmis system), the arms being operated by magnets, which are controlled by makers and breakers operated on by a striking board fixed on the last coach. The train in passing either breaks the circuit and puts the arm to danger, or makes the circuit and lowers the arm. Each station is equipped with a "home" and a "starter," the latter acting as a "distant." The circuit to lower the signals for the section in the rear of any station can only be completed if the "starting signal" is at danger—thus forming "absolute block." A train on leaving a station passes a breaker and puts the "starter" to danger, and after moving about 150ft. passes a maker, which completes the circuit and clears the section in the rear, leaving itself protected by the "starter." This system dispenses with signalmen, they only being employed where shunting operations are carried on. Each station is equipped with a crossover road interlocked with the signals. The total cost of the first portion of the railway, 5¾ miles in extent, was £90,000 per mile. The earning power of the railway as at first constructed, and which was only worked for traffic as far as the Alexandra Dock, was limited, as passenger traffic on the docks practically ceases at 6 p.m.; and this the directors foresaw, and in 1892 obtained powers to extend the railway both in a northern and southern direction. The northern extension, a quarter mile in extent, but opening up another three-quarters of a mile for traffic, was opened as far as Seaforth in 1894, and fully justifies its construction, the number of passengers carried having increased from 2,475,639 for the six months ending December 31, 1894, to 3,780,375 for the six months ending December 31, 1895.

Southern Extension.

The southern extension, five-eighths of a mile long, which is now in course of construction, commences about 150 yards north of the present terminus of the railway, with a viaduct 250 yards long, crossing Sefton-street and the Brunswick goods yard of the Cheshire Lines Railway, a portion of the Dock Board Estate, and entering the hill side at the north-east corner of the Herculaneum Dock, and proceeds in a south-easterly direction to Park-road. To meet the requirements of the Dock Board their land is crossed by one span of about 200ft., the main girders (which are of lattice type with parallel booms) being 220ft. and 225ft. respectively, and the whole of the span will weigh about 212 tons. Underneath where these big girders will rest at the face of the tunnel are casements for storing petroleum, belonging to the Dock Board, extending about 60ft. into the hill, and to distribute the weight of the span over these a bearing girder weighing 10 tons has been let into the rock, and on this girder the east end of the span will rest. The west end will rest on a pier provided with rollers and rockers. The normal tunnel has a span of 26ft. 2in. springing to springing, and 25ft. 6in. between side walls with a splayed plinth course; the arch is semi-circular. The tunnel for the station ground is 52ft. span, the arch being segmental, having quarter-span rise.

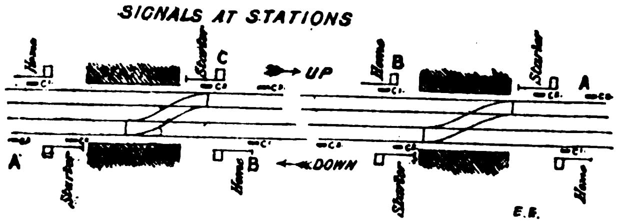


Fig. 2.

C^1, C^2, C^3 are contacts placed on brackets alongside the girders.
A Train passing over C^1 puts Home Signal to danger.
,, ,, C^2 puts Starting Signal to danger.
,, ,, C^3 pulls off Home Signal and Starting Signal of the Section in the rear.

The tunnel is under house property the entire length, and it was therefore not always possible to sink shafts where they were desired. Five shafts 10ft. square were sunk, from the bottom of which headings 11ft. and 12ft. were driven in each direction, and the greatest error in line and level was under ⅝in. The tunnel portion—about 800 yards—is almost entirely through red sandstone rock, which, like most of the rock in the neighbourhood of Liverpool, is of a very treacherous character. Heavy backs and wet clay beds being frequently met with, necessitating heavy timbering, a large number of the crown bars had to be built in. The tunnel has therefore had to be lined throughout its entire length; all the lining is faced with brindle bricks built in cement. Black powder has been the chief explosive used in the excavation. At about 170ft. from the entrance the tunnel crosses at an angle of 28° 27′ 40″ over the tunnel of the Cheshire Lines Committee Railway, through which the trains of the M. S. and L., G. N., and Midland Railways run, and the greatest distance that could be allowed between the overhead rails and the crown of the Cheshire Lines tunnel was 2ft. 9in.

After careful consideration the engineers decided that the only safe way to effectually make the crossing was by turning a segmental screen arch, five rings thick, built with brindle bricks in cement, over the Cheshire Lines arch, and to build the side walls of the overhead tunnel on this screen arch. This

Digitized by Google

was carried out as follows: A top heading 120ft. in length was driven along the crown of the Cheshire Lines tunnel, and then 8ft. lengths were excavated, baring the Cheshire Lines arch for that length. The exposed arch was then haunched with concrete and the screen arch turned on sand, with ½in. narrow boards placed on it, and when the arch was set the sand and boards were withdrawn, leaving a clear space of 6in. over the Cheshire Lines arch, so that no additional weight would come on the Cheshire Lines tunnel. During these operations all the rock above had to be carried on timber. To guard against possible fall of rock which might crush through the Cheshire Lines arch, before commencing the above operations a shield was put inside the Cheshire Lines tunnel. This shield was made of 8in. by 5in. H steel joists at 4ft. 3in. centres, bent to the radius of the tunnel, and carrying 4in. laggings, and keyed up tight by means of folding wedges to the soffit of the arch. The Overhead Railway Company had also to provide for the Cheshire Lines at some future time having to construct another tunnel on the east side of their existing tunnel, and to avoid any interference with the traffic during the future it was decided to build a length of tunnel arch seven rings thick, on which arch the Overhead Railway side walls are carried. All the excavation for this crossing has been done entirely by hand labour, and has proved a most expensive and anxious piece of work. Further on the tunnel passes under a 5ft. by 3ft. sewer, and to avoid disturbing this the arch was altered from semi-circular to segmental, which just permitted with care the sewer to be underpinned. The trains on entering the tunnel will be automatically lit up from copper conductors suspended from the roof of tunnel, collectors being fixed on the roofs of the carriages. These lights will be fed off accumulators, so that if a train should be stopped in the tunnel due to short-circuit on the line, the carriages will not be in darkness.

The terminal station of this extension is situated at Park-road, otherwise called the Dingle, below the road level. The underground station will consist of an island platform about 27ft., with suitable sidings for accommodation of the trains. The station will be ventilated by a large up-cast shaft. The access to the station will be by means of a subway at a gradient of 1 in 14. The booking offices will be on the road level. The station will be lit throughout by electricity, the underground portion by arc lamps at 110 volts, supplied by a transformer off the main current. Battery lights will be provided in the event of a short-circuit on the line. As the station platforms are considerably below the level of the sewers, the question of dealing with the drainage of the tunnel and sewage of water-closets and urinals had to be considered, and it was decided to employ Shone's hydro-pneumatic system. The drainage and sewage gravitates to the ejector, which is 50ft. from the surface, and gradually rises until it lifts the balance spindle which opens the compressed-air admission valve. The compressed air thus automatically admitted into the ejector presses on the surface of the sewage, driving the whole of the contents of the ejector into the sewer, and this is repeated automatically. The compressed air does not follow the sewage into the rising main which conducts the sewage into the Corporation sewer 50ft. above, but is at once exhausted from the ejector by the automatic action of the spindle, the great advantage being that no such straining of the sewage as is necessary for the proper working of ordinary pumps is required for the efficient working of the ejector. The capacity of the ejector is 50 gallons, and the quantity dealt with per minute will depend upon the amount of sewage and drainage water coming down. If necessary, the ejector would fill and discharge four or five times per minute. The compressed air will be supplied from a compressor which will also charge the trains with air, the pressure being reduced for the ejector from 80lb. to 20lb. The permanent way and main conductor will be of the same section as on the present railway, but the rails are laid on the usual cross sleepers with cast-iron chairs to distribute the pressure.

As more generating plant will be required to work the additional number of trains, it was decided to increase the size of the present generating station, and to run feeding cables a length of about two miles so as to regulate the E.M.F. instead of building another generating station, as it was found that this method would cheapen the working costs. The addition to the generating station consists of two engines built by Messrs. Hick and Hargreaves, and two new dynamos and switchboard built by Messrs. T. Parker and Co., of Wolverhampton. The two new engines are Corliss valve engines, each of the horizontal surface-condensing type, having cylinders 15½in., 31in. by 3ft. stroke, each intended to give 400 i.h.p. as an economical load when running at 100 revolutions per minute, with a boiler pressure of 120lb. per square inch. The engines are of ample proportions throughout, and are fitted with a steam-jacketed receiver between the cylinders containing boiler pressure steam. The beds are of the box type, and of heavy section. The flywheels are 14ft. diameter, and are grooved for 19 ropes, each 1¼in. diameter. The condensing apparatus is a separate plant, having its own air and circulating pumps. Among other features of the new engines are, first of all, the construction of the cylinders, which are of the four-valve Corliss type, and which, instead of being cast in one piece, as is usual, are each built up of four principal castings—namely, a working barrel, a jacket, and two end pieces containing the circular steam and exhaust valve chambers—thus substituting four comparatively simple castings, which can each be cast of the mixture most suited to its purpose for a single casting of so complicated a character that it can only be cast of a comparatively soft mixture, and it is even then liable to failure from initial stress aided by unequal expansion. This sub-division not only reduces the chance of disablement, but should such occur the defective part may be replaced with much less expense and delay than a complete cylinder. Both cylinders are thoroughly steam jacketed, the steam traversing the jackets on its way to the respective cylinders. The governors are rope driven, and are of a new design, especially intended to combine the powerful governor with one of great sensitiveness for dealing with great variations of load (a diagram is given showing fluctuations in load, see Fig. 3).

The output of each dynamo is 500 volts, 500 amperes, at a speed of 420 revolutions per minute. The armatures are so arranged as to be interchangeable, identical in the matter of external dimensions with the existing ones; the resistance from brush to brush measures ·010 ohm. The magnets, however, instead of being of the double horseshoe type as in the present machines, are of a single horseshoe, with the poles at the top. This has resulted in an increase of efficiency, the shunt resistance being now 100 ohms as against 75, making an electrical efficiency of 98 per cent. The loss in hysteresis, eddy currents, windage, etc., amounts to 6,000 watts, so that the commercial efficiency at full load will be about 95·7 per cent. The magnets are of special magnetic steel of the highest permeability, and are arranged with the patent hinged pole-pieces. This allows of ready access to the armature for inspection, cleaning, or lifting without the necessity of unsetting the bearings. The dynamos are rope-driven by 19 1¼in. ropes, the rope pulley running between two bearings and the pulley shaft being connected to the armature by a coupling, so that the armature can be changed without disturbing the ropes. The bearing at the commutator end of the machine is of the spherical type. The diameter of the shaft through the bearings is 5in., the length of each bearing being 1ft. 5in. The brushes are of phosphor-bronze lined with white metal, the top brasses of each bearing being slotted to receive two lubricating rings, the bottom brass being continuous. The total weight of the machine is 24½ tons, the armature being 3 tons 2cwt. The steel magnet casting alone, without winding, is 12 tons.

The main switchboard consists of six slate panels, with sets of switches and instruments—one set for each dynamo in generating station. Each panel is fitted with one patent double-pole automatic magnetic cut-out, with plate-glass shields to protect the attendant from the arc in case a short-circuit on the line causes the cut-out to open with excessive load. These cut-outs are also employed as main dynamo switches, being made and broken by hand for connecting the individual dynamos to the omnibus bars. The magnets of the cut-out are compound wound, so that the circuit is broken immediately in case of a reversal of current. One single-pole throw-over switch for connecting the dynamo circuit (beyond the automatic cut-out) either to the omnibus bar, which feeds into the central conductor at the nearest point to the generating station, or through a feeder to a distant point on the line to equalise the E.M.F. One 33-way sliding, regulating switch to vary the resistance in the dynamo shunt circuit for maintaining the E.M.F. of each dynamo constant. One set of double-pole plugs for connecting voltmeter to dynamo before paralleling. One "Weston" ammeter, indicating the current passing from each dynamo to the line. The slate slabs are held on wrought-iron framework, all connections at the back being of heavy cast-bronze rods, supported on pillars, so that all straps and connections are accessible, no insulated cable being employed. The front of the board is finished off with massive teak carved pillars and panels.

Besides the instruments already described there are four "Weston" voltmeters, with illuminated dials, and an engine-room clock supported on panelled framework above the slate slabs. The voltmeters are arranged as follows: one connected directly across the omnibus bars; one for connecting at will to any dynamo by means of plugs to take E.M.F. before paralleling; one for connecting across brushes of the dynamo running on the feeder circuit; one as pilot voltmeter connected to the distant point in the line where feeder is coupled.

To meet the increased traffic that is expected from the southern extension, new rolling-stock is being built by Messrs. Brown, Marshall, and Co., and as the number of passengers carried is now over 7½ millions a year, the directors have found it necessary to increase the size of the trains by composing them of three carriages instead of two. In fact, last half-year (excluding bank holidays) an average of 60 per cent. of the seating accommodation of the trains was occupied. The new motors built by the Electric Construction Company are very similar to those at present in use, their strength being increased

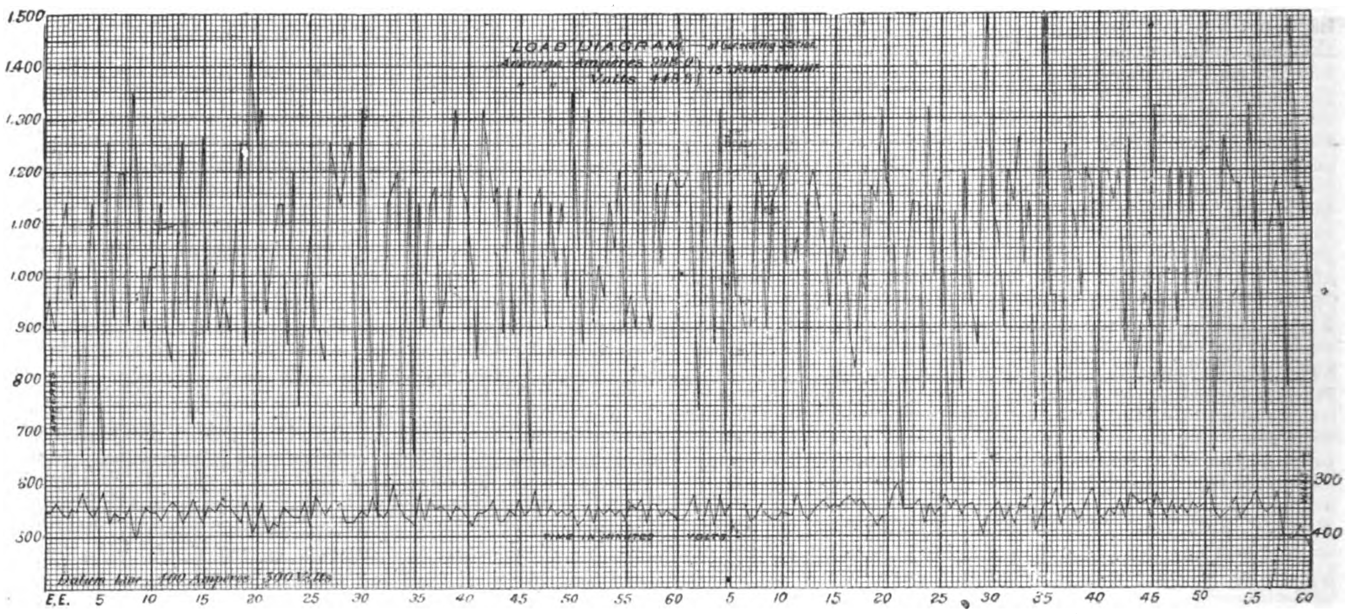

Fig. 3.

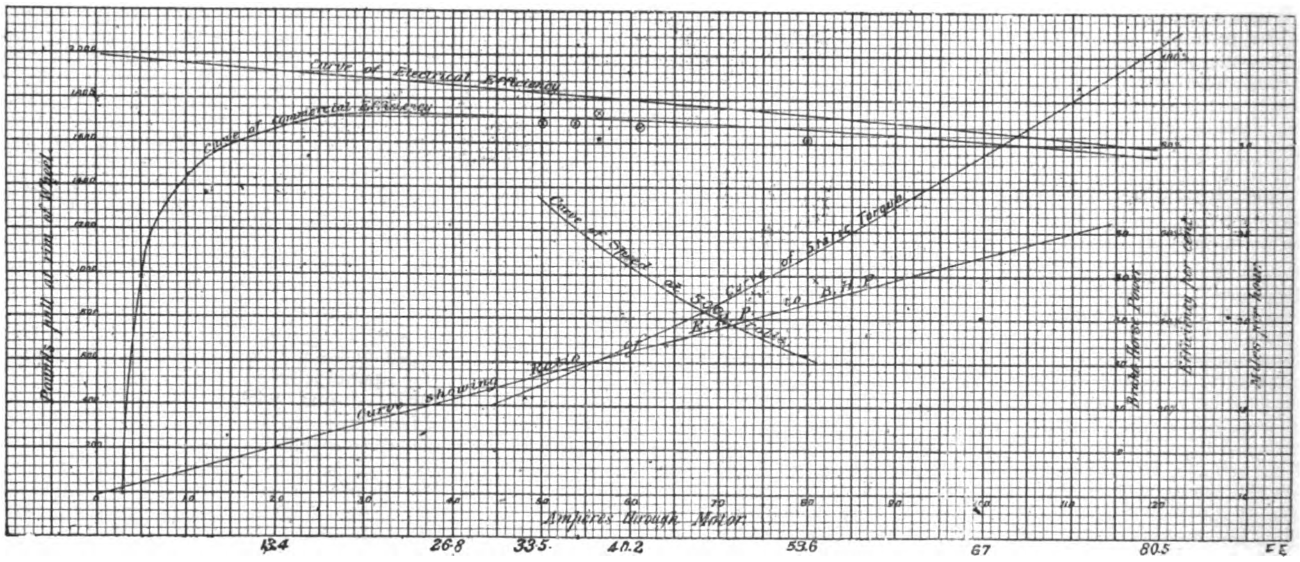

Electrical Horse-Power delivered to Motor, corresponding to above Amperes at 500 Volts.

Fig. 4.—Curves of Torque, Efficiency, and Speed of Liverpool Overhead Railway Motor.

Static Torque Curve, taken in usual way, by bolting lever on shaft, and weighting it at measured distances along it, till pull of current through motor is balanced.

Electrical Efficiency Curve takes into account the C^2R losses in the copper only. Resistance of armature and magnets in series is ·83 ohm, at a temperature of about 70deg. F. above atmosphere.

Commercial Efficiency Curve shows actual efficiency of motor at wheel, and is obtained by estimation of all the losses separately. The motor was made to drive a dynamo by a belt. The small discrepancy between these points and the Commercial Efficiency Curve is accounted for by the necessary approximate allowance made for belt, though this was as accurate as circumstances would permit.

As this new rolling-stock will only be a small portion of that owned by the company, it will be necessary to increase the number of carriages in the present trains, but as the first motors were only designed for two carriages, experiments have been made with a train fitted with a new and very ingenious form of roller bearings designed by the Roller Bearing Company. It has been shown by the falling weight test that this train will start at a reduction of more than 80 per cent. in starting effort over a train fitted with ordinary bearings, and therefore the company will be able by slightly modifying their present motors and adopting roller bearings to increase the carrying capacity of all their trains by adding an additional carriage.

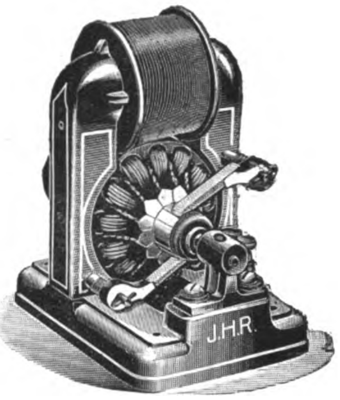
The engineers for the southern extension have been Sir Douglas Fox, M.I.C.E., and Mr. J. H. Greathead, M.I.C.E., and the author has acted as resident engineer, assisted by Mr. Norman and Mr. Fright, and the contractors have been Messrs. Pearson and Knowles for the viaduct portion, and Messrs. H. M. Nowell and C. Braddock for the tunnel portion.

The railway has now been working for over 3½ years, and it has proved that working on the zone system as regards fares and having only two classes is the best for railways of its character, the value per passenger being 1·97d., as against 1·75d. on the Metropolitan Railway in London, whose fares are very much higher than on this railway. The zone system allows an economy of about 25 per cent. on the staff, and as tickets are only used for first-class passengers there is considerable economy in printing.

The maintenance of the line is naturally very heavy, as there are alone over 80 acres of surface to be protected from corrosion, of which 20 acres are painted with an oxide paint and remainder with black varnish, and at the present it is being painted at the rate of once in two years. During this year experiments have been made with a pneumatic painting machine, which blows the paint on, the result being to reduce the cost from 2·25d. per square yard to 1·24d. per square yard, including all materials. The motors now run an average of 40,000 miles before requiring repairs, in which time they earn over £200, and can be rewound at a cost of £25. The company has at the north end of the line fully equipped workshops, where they carry out all their own repairs. In the appendix will be found a comparative statement of receipts and expenditure, and dissection of locomotive expenses, and Fig. 5 gives curve of electrical horse-power for one train. Further detail of the first portion than I have described to you will be found in the publication of the Institution of Civil Engineers, vol. 117, in papers read before the members by Sir Douglas Fox, vice-president, M.I.C.E., and Mr. Greathead, M.I.C.E., and also by Mr. Thos. Parker.

THE RIGG MOTOR.

The demand for small motors for household and factory use is increasing, and we are glad to note that English manufacturers are taking up their production on a large scale. The larger proportion in the prime cost of these motors is due to labour, and hence any simplifications of design tending to reduce the labour charges are most valuable. The subdivision of labour and interchangeability of parts, which can only be satisfactorily introduced when manufacturing in quantity, will enable foreign competition to be resisted. The Rigg motor, as illustrated herewith, shows a convenient type for small sizes.



The Rigg Motor.

The characteristics of this motor are as follows: The armatures are built up of charcoal-iron plates mounted on gunmetal spiders, and are of the iron-clad type; the shafts are of best cast steel, running in gunmetal bearings. The armatures being iron-clad the air-space is very small, and so the energy required for exciting the field is kept down to a small portion of the total power required, and the motor is consequently efficient. The field magnets are of special cast iron in the smaller and cast steel in the larger sizes, and mounted on a brass bed. The motors are well insulated, well made, and very efficient, and are wound for from 2 to 100 volts, either shunt, series, or compound. The whole of the component parts of the motor are simple in design, and the field-magnet construction requires little machine work, and there is no doubt but that the iron-clad type of armatures give great advantages in a small-sized motor.

Fatality on the Liverpool Overhead Railway.—Alex. Dallas, aged 61, who was formerly staff-sergeant of the Scottish Fusiliers and had served in the Crimea, was killed on Sunday afternoon by a train on the Liverpool Overhead Railway. It is supposed he was alighting after the train had started, for he was seen to fall between the footboard and the platform.

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE OUTLOOK.—No. 2.

In our article last week we confined our remarks almost entirely to electric lighting. The Brush meeting, of course, gave us our text as it gives us one again to-day. Of course we are harping back upon an old hobby, one we have trotted forth on many occasions. Our views, however, on these questions, as on many others, have, unlike the prophetic ones of those who prophesy without good ground to go upon, turned out approximately correct. In the first place, then, we do not believe that any English company is going to largely extend its sphere of operations in the direction of electric tramways for some time to come. If the immediate business of any company is dependent upon tramway work, it will prove a broken reed. There is always, of course, the retort that directors and people behind the scenes know better than newspaper scribblers. Generally that may be so, specially it is altogether wrong; and we imagine our means of obtaining information is better than that of any individual firm, or, indeed, of half a dozen combined. It is true that a number of schemes for electric traction are floating about, and we think we could almost state into whose hands the work would fall if the financial *pourparlers* prove successful. A long time, however, is likely to pass before many of these schemes are ripe. This conclusion does not mean that we are despondent about the final success of electric traction, but that for many reasons its development in this country will not be rapid. It might be otherwise if any firm could guarantee self-contained cars worked electrically at somewhere about the cost of horse traction. Our remarks do not extend to foreign or colonial development. Here, however, we are brought face to face with Continental and American competition, both competitors very keen, both having more experience, and both very much alive to the openings where such traction is possible. Thus while our factories may obtain a few orders, an extensive demand is hardly to be expected at once. Let us not be mistaken; we are neither optimists nor pessimists, but prone to take things as they are rather than to take them as interested parties would like them to be.

There is a direction in which we imagine, with careful management, development should take place fairly rapidly, and if this should be the case, the larger factories ought to benefit to a considerable extent. The distribution of power is extending in England as most new ideas extend. A few of the more advanced have taken it up, and these have been followed till quite a number of factories employ motors for driving machinery. The latest indication of the progress of this class of work is to be found in the presidential address of Colonel H. F. Swan to the North-East Coast Institution of Engineers and Shipbuilders on Wednesday last. Colonel Swan, among other things, says:

"There is no question that electricity is destined to play a very important part in connection with shipbuilding in the future, both as regards portable appliances and also the general driving of the shop machines. It of course involves a certain amount of courage, not to speak of a large expenditure of

Digitized by Google

capital, to abolish existing steam-engines, boilers, etc., and replace them entirely by electric power. Some establishments are therefore dealing with the matter tentatively, whilst at Hartlepool one of the chief yards has been laid out for electric driving entirely, thus abolishing several isolated boilers and steam-engines and dispensing with the necessary attendants, and, in addition, obtaining the facility of being able to use only such individual machines as are actually required from time to time instead of having, as at present, all machines going, whether wanted or not, which with the loss of power by transmission through long lines of main shafting, counter-shafting, pulleys, belts, etc., involves a total loss of the power transmitted varying from 30 per cent. to as much as 70 per cent."

We believe it is absolutely correct to say that wherever electricity has been properly tried for such factory work it has been proved better and more economical in every way. Broadly speaking, this economy was foreseen, and has been referred to many times by us. The concentration of engines and boilers, and the greater economy thereby both in fuel and wages; the getting rid of the constant drain upon the power developed from rotating shafting, pulleys, etc.; the using in the machine just what power is wanted for the exact time it is wanted; the greater cleanliness, and so on, were bound to lead to economy. More and more factories are adopting the method, and more will follow, so that business ought to be brisk in this direction. One feature that tells against our factories is their inability to hold the trade in small motors. These in most cases are obtained from the Continent or from America, a state of affairs worthy of attention. Lastly, for our purpose at the present moment, we would direct attention once more to the economics of central-station work. Here you have a mass of costly machinery standing idle most of its time, or moving merely to supply a few lamps. This machinery in many places ought to be earning income. Power is required by small users as well as large. If they could, the former would have it from the central station. Sometimes a separate set of power mains would be necessary, but the return would be enormous compared with this initial cost and annual maintenance. The stumbling block is that designers in England have not catered for the possibilities of power work. They have in places stuck in alternate-current plants where direct-current would be better. They have, further, stuck to single-phase work rather than diphase or triphase, although for motor work the single-phase is probably the most difficult wherewith to obtain satisfactory results. Again, we must qualify ourselves; there are many stations where light, and light only, has to be considered. Our contention is that in other stations, where power distribution ought ultimately to be the more important and the largest earning factor, it has not been considered at all. We have been more than once told that English people would be frightened at the larger initial expenditure required, and to act on these views would retard rather than hasten the demand for electrical apparatus.

REVIEWS.

The Principles of the Transformer. By FREDERICK BEDELL, Ph.D. The Macmillan Company.

This volume is an amplification of a work commenced by Dr. Crehore and the author in 1891. The joint authorship resulted in a series of articles published in the *Electrical World* on the theory of the transformer. In the present volume much new matter has been added, and the special treatment of several problems is decidedly new. The author has not confined himself to the mathematical and graphical treatment of the subject, as seems to be the case when the book is first turned over, but has incorporated many useful hints on the practical side of the subject. The first chapter deals with the different transformer systems of distribution. Diagrams of how to make and how not to make the necessary connections outside the transformers are given, and several general conclusions are drawn. Thus the author is not a blind advocate of alternate-current work, but considers that "the direct current may be used to advantage in districts, all parts of which are within about half a mile of the central station," but that "beyond that distance it can rarely be operated economically." He also refers to the fact that although in thickly-populated districts the direct current can be commercially successful, over larger areas it may be that the alternate-current system would give additional profit. The diagrams of connections given for placing transformers in parallel on low-tension mains or to supply on to a three-wire network are worthy of attention, as many interruptions in a town supply have resulted from faults in this direction. In the next chapter the reader is primed with the symbols and conventions used throughout the book, and we are pleased to see that as a rule the symbols agree with those used in this country. The letter N is said to refer to magnetising force, but we fancy this must be a misprint rather than an innovation, as H seems to be invariably used throughout the following pages. J is used for impedance, and I for current, which will be rather strange to the English reader at first. The convention as regards the various values of the different harmonic variants is as follows: The plain capital denotes the maximum value, the same capital with a bar over it denotes the virtual value—*i.e.*, the square root of the mean square of the instantaneous value—and the small letter stands for the instantaneous value. These conventions and several others save a large amount of space and writing, and are worth acquiring. The third chapter starts the theoretical treatment of the transformer by dealing with the magnetic circuit, and a fair knowledge of mathematics is required to read the subsequent chapters. To anyone taking up the subject with leisure, the mathematical and also the graphical treatment will be most interesting. We confess our preference for the graphics, and the fact that most of the diagrams are constructed to agree with the characteristic of real transformers adds to their value. On the question of the shape of the current curve the author assumes that all shapes can without appreciable error be treated as sine curves. This does not assume that the current and E.M.F. curves actually are harmonic, but that an harmonic current and harmonic E.M.F. can be found to give similar effects. This is not rigorously correct, but it simplifies the treatment greatly. Special cases can be investigated by the aid of Fourier's series of sine functions if absolute accuracy is required. The author in the chapters on the alternate current and on the simple transformer diagram leads the student gradually up to the subject as treated graphically before he really commences the analytical theory. This enables a physical conception of the phenomena to be obtained. The various complicating secondary effects—such as the action of magnetic leakage and of condensers in either the primary and secondary circuit—are treated in the following chapters, and in all cases polar diagrams are found to be capable of solving the problems. In the fifteenth chapter the more practical part of the subject is again commenced, which will repay careful reading. The history of the transformer is dismissed in a few pages in favour of the principles of design. The following extract will show how fully the

Digitized by Google

author is in accord with the requirements of the present time: "In the design of any apparatus the aim of the designer should be to produce the desired result with the smallest yearly expense. The yearly expense includes not only maintenance, interest, and attendance, but also the cost of power wasted in the apparatus, a just allowance for repair, and also for depreciation and final replacement. The ideal design must be based upon a consideration of each of these items of yearly expense as affected by the particular conditions under which the apparatus is to be operated; the best design for one set of conditions may not, and probably will not, be the best for other conditions." The author frankly acknowledges that a complete analytical treatment for designing transformers commercially is impossible, and that trial and error methods must be adopted in getting out new types. He then proceeds to discuss the proportions of cores and winding likely to give the best results, and by extreme cases shows what is to be avoided. The subdivision of coils and the relative position of primary and secondary winding to prevent magnetic leakage is also referred to in general terms. We are surprised, however, to see a statement that oil in the case improves the coil insulation. That the coils so immersed are less likely to break down from sparking we know, but as a general rule the insulation resistance is lowered. A few practical designs are given, and then the author makes some computations as to the all-day efficiency of different transformers under certain assumed loads. The methods of obtaining experimental diagrams as described in the following chapter are interesting, and the standard method of testing transformers forms the subject of another chapter. On the whole, the book tends to advance the abstract rather than the practical treatment of the subject, but it is a valuable addition to the literature on transformers.

ON THE MULTIPLICITY OF BRUSHES IN LARGE GENERATORS.*

BY WILLIAM BAXTER, JUN.

When multipolar generators first came into use there was quite a difference of opinion as to the proper number of brushes. German builders adopted the plan of making the number equal to the number of poles, but the English electricians maintained that this complication was undesirable and inexcusable, inasmuch as it could be avoided by the simple process of cross-connecting the commutator. American engineers, as a rule, were in favour of single brushes in the early days, but they soon changed to the multiple system; and at the present time it is doubtful if a manufacturer can be found who does not follow the latter construction.

The reason for this change from simplicity to complication is to be found in the fact that carbon brushes came into use at about the time when the multipolar machines were being introduced; and as these brushes are of a much lower carrying capacity than copper, the number in parallel, or in other words their cross-section, must be increased. This, as is evident, can be done in two ways, one of which is to widen the face of the commutator so as to place a greater number in a row; and the other is by placing brush-holders at all the equipotential points and connecting the alternate ones in parallel. If the latter plan is adopted the face of the commutator can remain of the normal width, and this fact is, in all probability, the chief cause for its adoption, it being believed, no doubt, that the cost of construction would thereby be reduced and a more symmetrical design obtained. It is by no means certain that the multiplicity of brushes reduces the cost of construction or that it renders the design more symmetrical; but even if it did its adoption could not be deemed advisable for these reasons alone. There are two things to be considered in all such cases; the first and most important one is the effect upon the operation of the machine, and the second the cost of construction.

A very little reflection will show that the two-brush machine will prove the most satisfactory to the user, and will be subject to less deterioration, owing to the fact that it will be better taken care of. If there are but two brushes, they can be located at any point on the periphery of the commutator, where they will be most accessible, and this fact of itself will ensure their receiving better attention. If multiple brushes are used, this may not be the case; in fact, it is almost sure not to be. The brushes on the sides and on top of the commutator will receive proper care, but those underneath will not, for even the most faithful attendant cannot be expected to watch as closely these inaccessible parts, and it is very probable that the owner himself would neglect them if he had to take care of the machine. Many men maintain that such objections amount to very little, that the attendants are paid for their services, and if they do not perform their duties faithfully they can be discharged and better men obtained; but the fact is, as everyone who has had experience in such matters knows, that it is difficult, if not impossible, to find men who will give just as much attention to inaccessible parts as they will to those that can be reached without inconvenience or danger. Another objection to the use of multiple brushes is the difficulty involved in adjusting them to the non-sparking points. This is by no means an unimportant matter, for upon it depends the life of the commutator to a very great extent. Unskilled men very often find it difficult to set a single pair of brushes so that they will not spark; such being the case, what can be expected when multiple brushes are used? If all the men who take charge of electrical machines were competent, the difficulty of adjusting multiple brushes would not be very much of an objection, but the number of incompetent men is very great and is constantly on the increase. There was a time when those who knew nothing about electrical machinery would not attempt to take care of it for fear of being killed by a shock, but any number have now found out that there is no such danger with incandescent lighting generators, and the result is that there are engine attendants everywhere who claim to be expert in the care of generators simply because they have had charge of one for a few months. The fact that the proper adjustment of multiple brushes is beyond the capacity of the majority of the men who are in charge of machines of that type can be verified by an actual inspection of isolated plants. Two-pole generators that run sparkless can be found everywhere, but a sparkless running multiple brush machine is the exception, and this is true even in plants of several hundred kilowatts capacity.

If these points are well taken, then it is evident that machines with a single pair of brushes are the most desirable from the standpoint of the user. They will be kept in better adjustment, not only because it requires less skill to do so, but also because the parts are more accessible and therefore can be given the proper attention without inconvenience.

The sparking of multiple brushes is not always the fault of the attendant. In many cases it is due to the fact that the various parts of the machine are not in accordance with each other, and therefore the non-sparking points either shift backward and forward as the armature rotates, or else are never in line with the brushes. If the brushes are placed at equal angles around the commutator, they may and they may not rest on the non-sparking points. If the commutator segments and the armature sections are equally spaced, and the magnetic circuits are of equal strength, and the fields symmetrical, the equipotential points and the position of the brushes will agree, but under any other condition they will not. It is difficult to obtain exact agreement of all these points, therefore it is difficult to obtain a non-sparking condition with multiple brushes. The result is accomplished by the best manufacturers, but only by the exercise of the greatest skill in the design and the greatest accuracy of workmanship in the construction.

With two brushes all these difficulties are considerably reduced, and the same amount of skill and accuracy of workmanship will produce better results, or, more properly speaking, such a machine of equally good design and construction can be adjusted to run with less sparking. The reason for this is that if there are as many brushes as there are poles, each one must rest on a neutral point to avoid sparking. If the fields are not symmetrical and of equal strength, the neutral points will not be equally spaced around

* From the *Electrical World*, New York.

Digitized by Google

the commutator, and therefore it will be impossible to have all the brushes on the line. If only two brushes are used this difficulty will not be encountered; if the armature is wound with the equipotential sections in series, the irregularities in the induction of the several magnetic circuits will, to a very great extent, counteract each other, and as a result the difference between the arc separating the brushes and that between the neutral points on the commutator, with which they come in contact, will be so small as to produce little or no sparking tendency. If the armature is connected in parallel, the inequalities of induction in the several magnetic circuits may shift the position of the neutral points on the commutator, but as only two of these are in contact with the brushes, two can be adjusted so as to nearly agree with each other sufficiently well to obviate practically all sparking.

If the series connection of the armature could be used in every case perhaps the majority of engineers would be in favour of the two-brush system, as then the cross-connection of the commutator would not be necessary. It is very generally believed that a cross-connected commutator is not as reliable as one not so made, and also that it is expensive to manufacture. These notions, however, are not correct; there are simple ways of cross-connecting that are perfectly reliable and not at all expensive—in fact, as far as cost goes, the saving of the brush-holders, and ring for supporting them, would more than pay for the additional expense placed on the commutator by the cross-connecting thereof.

In the early days of multipolar generators there was a valid reason for not using two brushes, which was that as carbon brushes were used the surface of the commutator would have to be widened. Since that time, however, woven wire brushes have come into use, and have been found to be equal, if not superior, to the carbon. The carrying capacity of these is so high, and the resistance of contact so low, that, with them, extra width of commutator would not be necessary.

The writer has many times tried to find out why everyone adheres to the multiple brushes, but has thus far failed. In almost every case the reason given is that the matter has been thoroughly investigated and the latter arrangement found to be the best. This is a very indefinite although easy way of disposing of the case, but it proves nothing. A great many men may have come to the above conclusion after a thorough investigation of the matter, but others, and perhaps a greater number, after a similar investigation have come to the opposite conclusion. To the writer it looks very much as if this were another verification of the old saying that men's minds run in grooves. There are very few leaders, and most everyone follows in the footsteps of those who are successful. As the large concerns have adopted the multipolar construction, the smaller ones fall into line and do the same thing, because they are afraid to strike out on an independent track. Perhaps some day a concern of more than ordinary courage will depart from the beaten path and place on the market two-brush machines. If such a thing should come to pass, we would be able to find out in a practical way which system is the best. In the opinion of the writer the two brushes would come out victorious.

SCREW GAUGE.

Report of the Committee, consisting of Mr. W. H. PREECE (*Chairman*), Mr. CONRAD W. COOKE (*Secretary*), Lord KELVIN, Sir F. J. BRAMWELL, Sir H. TRUEMAN WOOD, Major-General WEBBER, Mr. R. E. CROMPTON, Mr. A. STROH, Mr. A. LE NEVE FOSTER, Mr. C. J. HEWITT, Mr. G. K. B. ELPHINSTONE, Mr. T. BUCKNEY, Colonel WATKIN, Mr. E. RIGG, *and* Mr. W. A. PRICE, *appointed by the British Association to consider means by which Practical Effect can be given to the Introduction of the Screw Gauge proposed by the Association in* 1884. *(Drawn up by the Chairman.)*

I. THE PAST.

A uniform system of screw threads was first proposed by the late Sir Joseph Whitworth in 1842, and his thread, a compromise of the numerous threads then in use, has become of almost universal use for all large screws—that is, screws of over ¼in. in diameter—in the United Kingdom. Mr. William Sellers, in 1864, introduced another thread in the United States of America, which has come into very general use in that country, and this thread has recently been accepted by the French. In 1881 the British Association formed a committee to determine a gauge for the manufacture of the various small screws used in electrical apparatus, clockwork, and for other analogous purposes, and after three years of unremitting labour this committee, in 1884, recommended a screw gauge which has come into very general use in this country. It was based on the metrical system, and, with one slight modification, on the system adopted in 1880 by the Swiss watchmakers. The series of screws recommended is given in Table I.

TABLE I.—British Association Screw Gauge.

Number.	Dimensions in millimetres.		Dimensions in thousandths of an inch.		Threads per inch.

25	0·25	0·072	10	2·8	353·0

The form of thread adopted was triangular, the sides forming an angle of 47½deg., with the top and bottom rounded off to two-elevenths of the pitch. The diameter, D, is related to the pitch, P, by the formula $D = 6\,P^{\frac{6}{5}}$, all measurements being in millimetres, and P having successively the values: 1 (or $0{\cdot}9^0$) millimetre; $0{\cdot}9^1$ millimetre; $0{\cdot}9^2$ millimetre; $0{\cdot}9^3$ millimetre; . . . $0{\cdot}9^n$ millimetre. The index n thus becomes a convenient number designating the screw.

The reasons supporting these recommendations were fully given in the report submitted by the committee at the Montreal meeting of 1884. Experience has justified the adoption of this gauge, which is almost universally used by the electrical trade, and is very considerably employed by the clock and instrument makers in the United Kingdom. It is not proposed to modify it, but there has been great difficulty in obtaining accurate gauges. No official system has yet been adopted by which manufacturers can compare their gauges with the standards, nor has a home been selected to deposit authorised standards for easy reference. British Association screws bought to-day from any screw manufacturer are not necessarily of the same dimensions as those supplied by the same maker a month ago. Screws supplied by different makers vary considerably from each other. Measuring gauges now existing, both male and female, differ largely from one another, and do not give correctly the true form of thread specified in the original report. The essential element of the value of screws made to a standard gauge—their interchangeability—has thus never been fully realised.

The British Association, having had their attention called to these anomalies at their last meeting (Ipswich, 1895), appointed a committee to consider the subject, which has now the pleasure to submit its first report.

II. THE PRESENT.

The committee was formed "to consider means by which better practical effect can be given to the introduction of the screw gauge proposed by the association in 1884." It has held many meetings. It has added Colonel Watkin, C.B., R.A., Mr. E. Rigg, and Mr. W. A. Price to its number. It has received great assistance from the Pratt and Whitney Company, of Hartford (Connecticut, United States of America), who supplied each member of the committee with a copy of their book on "Standards of Length and their Practical Application." It was unfortunately deprived of the services of Mr. Hewitt, who was seized with a very severe illness after the first meeting,

Digitized by Google

but it received from him his paper "On the Manufacture of Standard Screws for Machine-made Watches," read before the Institution of Mechanical Engineers in October, 1894, a paper which has been of great service. Mr. Griffith, representing the council, attended regularly, and took advantage of his presence in the United States of America to visit the Pratt and Whitney works. Evidence was taken by the committee from large users of the screws. Mr. Willmot, of the Post Office Factory, stated that the Post Office had used some tens of millions of screws made to the British Association gauge, and he had never received a single complaint. Various apparatus for measuring screws and different methods of testing their accuracy were carefully considered and discussed. The committee came to the conclusion that it was necessary to consider the subject from the three points of view of the Standards Office, the works manager, and the workman.

1. *The Standards Office.*

This must include not only the custody of recognised and authenticated standards, but also a scientific mode of measuring the dimensions of commercial gauges and screws themselves, and of comparing their accuracy with the authorised standards. The peculiarity of the British Association gauge is this, that material standards are not imperatively necessary. The table of dimensions given (see Table I.), together with the formula, enables any draughtsman to reproduce the form and pitch to any desired scale on paper. Colonel Watkin has shown to the committee how to throw side by side for purposes of very accurate comparison a photographic image of (*a*) the screw to be examined; (*b*) the standard with which it is to be compared; (*c*) a scale which may be divided to 1-10,000in., the images of these three objects being so close to one another that a comparison to a very high degree of accuracy can be made. The appendix to this report contains a description of Colonel Watkin's method.

Mr. Price submitted to the committee a microscopical method of measuring screws. This is described in the appendix. The screw to be measured is attached to the stage of the microscope, the traversing slide of which is provided with a vernier and scale, while a vertical cross-hair in the eye-piece forms the index of the instrument. When the microscope has been adjusted for clear focus the screw is traversed across the field until the cross-hair intersects the thread of the screw at the desired point. The traversing screw of the slide is then turned until the corresponding point of the next thread is intersected by the cross-hair, and the reading of the vernier on the scale gives the measurement of the pitch with great accuracy. Mr. Buckney showed also how the angle of the thread could be accurately verified by this method by having suitable h airs.

2. *The Works Manager.*

The committee, after considering various methods, came to the conclusion that male gauges for ordinary workshop use were best tested as regards pitch and form of thread by a template or "comb" for each number, the accuracy of which has been verified by the photographic method. The screw to be tested is placed against the teeth of the comb, and the correctness of its fit verified by the eye against a light background. The external dimensions of the screw can be obtained by any good micrometer gauge, and the internal diameter or core by a gauge such as that which is described in the appendix by Mr. Stroh. The committee have failed to discover any very reliable method of testing to any degree of accuracy a female standard gauge. No clearance was allowed in the original definition of the system between the male and female standards. Hence a mathematically accurate male gauge cannot be screwed into a mathematically accurate female gauge. But by allowing a certain margin—a maximum and minimum diameter—an internal compatibility of dimensions is allowed in the workshop gauges, which is of a sound, practical character. The female screw must always be a little larger than the standard male gauge, but this must never exceed what is known as a "good fit." A working margin is given in Appendix III., by a table, prepared by Mr. Le Neve Foster. Mr. Price, on behalf of the committee, has made a series of measurements of certain sizes of British Association screws which show the limits which they are obtained in practice. The table (Appendix IV.) indicates that the variation from the full diameter, which must be allowed for necessary inequalities in manufacture, is not a function of the diameter, but is rather in the nature of a constant quantity. This quantity appears to be approximately one mil below the full diameter for all brass screws of sizes Nos. 0 to 11, and 1·3 mils for all iron and steel screws of the same sizes.

3. *The Workman.*

The measuring gauge, available to the workman as well as to the foreman, is one that need not possess the mathematical accuracy of the standard gauges, but nevertheless it must not be allowed to deteriorate or to maintain false belief in its accuracy. Those that are subject to pressure and friction must necessarily wear, become distorted, and in time inaccurate. Hence, the committee were anxious to obtain a mode of comparison which would be free from this source of error. The most important measurement, whose accuracy should be easily verified by the workman, is that of the pitch, and this is easily effected with the "half-nut gauge" described in Appendix II. The committee are pleased to find that the result of their enquiry and discussion enables them to recommend for general use means of comparison which do not involve the wear and deterioration of the gauges. Deformation is confined to the taps and screw-plates, and as frequent verification of the manufactured screw is desirable, continued accuracy is ensured. With the introduction of simple methods of comparison and measurement errors in the screws issued, and want of interchangeability are rendered improbable in a well-regulated shop, and unnecessary in any place. There remains now to determine a place where material standard gauges are available for immediate comparison and where the photographic and microscopic methods can be readily applied to verify gauges and to obtain a record of those submitted for examination. This means work to be done, expenses to be incurred, and fees to be paid, as is now done at the Kew Observatory for chronometers, thermometers, etc.

III. The Future.

The opinions formed by the committee after full and exhaustive discussions for furthering the objects to be attained, may be summarised as follows: (*a*) This committee recommend the construction and housing of the comb form of gauges or templates of the British Association screw thread, by comparison with which master gauges or templates may be exactly and conveniently verified. (*b*) That as no exact system of testing female threads has yet been devised, the committee restrict themselves to recommending means for keeping male threads to gauge, and this they consider will be sufficient for the purpose of securing practical uniformity in female screws. (*c*) Male threads can best be measured by the comb, combined with suitably-arranged tests to give the correct diameters. (*d*) That for purposes of verification or standardisation the gauges to be deposited for reference should consist of a complete set of these comb-pieces and a complete corresponding set of male screws, so that new combs can be compared with those deposited, or male screws can be compared with the standard combs with great accuracy by the photographic or the microscopic method, and that these two methods may be conveniently used to check and corroborate one another. (*e*) That in order to obtain interchangeability of these male screws for practical workshop use it is sufficient that they should satisfy the following tests: (1) There should be no appreciable difference in the fit of the screw with a standard comb having not less than 12 teeth. (2) The diameter of the core must not exceed that laid down by the British Association specification. (3) The diameter of the screw measured over the thread must not exceed that laid down by the British Association specification. (4) The diameter of the screw measured over the thread must not fall short of that laid down by the British Association specification by more than a certain amount, which amount depends on the class of work and purpose to which the screw is to be applied. The amount referred to in (4) must be settled by the persons in control of the work for which the screws are to be used. (*f*) They recommend for general use in the workshop the half-nut gauge, as described in Appendix II., combined with inside and outside diameter gauges.

The committee, in printing the two tables, for which they have to thank Mr. Le Neve Foster and Mr. Price, do not take the responsibility of recommending any limits, but publish the information as an indication of the limits of accuracy to which these screws may be expected to be produced in practice. If the recommendations of the committee be approved of, they further recommend that the committee should be reappointed for the purpose of obtaining and verifying standard combs and male screws, and determining the future home of the gauges.

APPENDIX I.

Enlarged Shadow Photographs of Screws. By Colonel Watkin, C.B., R.A., etc.

The objects aimed at in producing enlarged photographs of screws are: (*a*) To provide a means of verifying the accuracy of the shape of a thread; (*b*) to provide a means of accurately gauging the dimensions of screw threads; (*c*) to provide a record or certificate of a screw in a similar manner to the certificate of accuracy given by Kew Observatory.

As in this process a standard scale is photographed at the same time as the screw, a direct reading to any desired accuracy can be obtained. There seems to be hardly any limit to the amount of enlargement, as the difficulties inherent to the enlargement of an ordinary negative do not apply to this process.

The question arises, does the shadow photograph give accuracy as regards (1) dimensions, (2) shape of thread? To test (1) a No. 2 British Association thread was enlarged 37·18 times. The linear dimensions could in this photo be measured to at least 1-5,000in. The diameter, pitch, and angle of thread of this particular screw were gauged by a member of the committee, and found to be:

Digitized by Google

By an Elliott gauge .... 0·1818 } diameter.
By a Brown and Sharp gauge 0·1820 }
0·03184 pitch.
54°·30′ angle of thread.

The photo gave the following:

0·1818 diameter.
0·03181 pitch.
54°·30′ angle of thread.

Fig. 1 shows a reduced copy of an actual photograph and scale. As regards (2) there has been considerable discussion as to

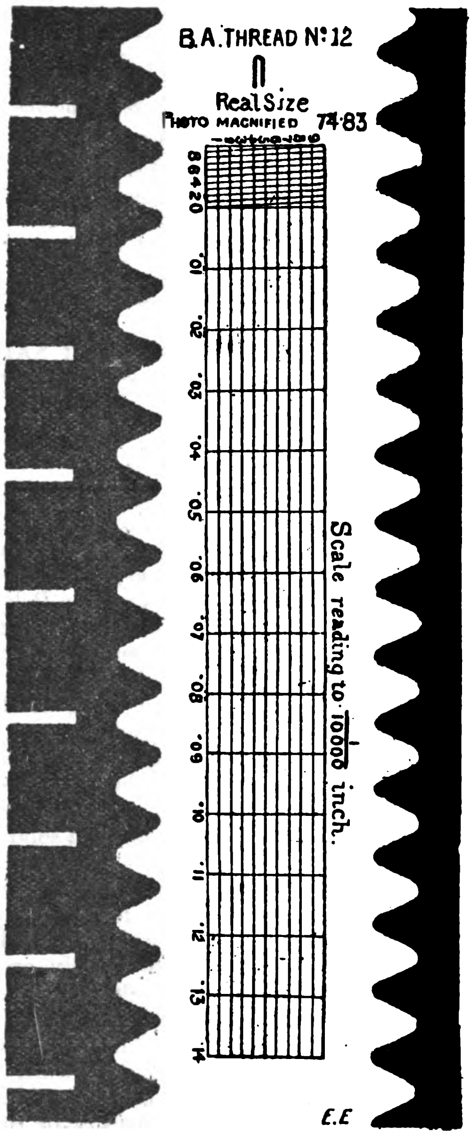

FIG. 1.

method, a mathematical consideration worked out by Mr. Price seems to show that a slight correction of about ⅓deg. in the total angle of the screw thread would have to be made. I think, as regards the second method, no correction is required. In any case, the correction is so small that for practical purposes it might be neglected, as on a No. 2 British Association thread it only represents about 1-7,000in., and proportionately less on the smaller sizes.

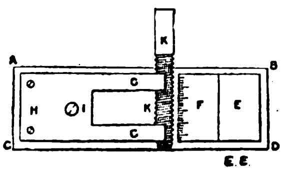

FIG. 2.

However, to determine practically whether this was the case, I suggested filing away a part of the screw to be photographed to make it a comb. There could be no doubt that the photo of such a comb would give the true shape of the thread. Mr. Stroh kindly supplied such a screw. From the photos it would appear that there is no practical difference in the shape, and that therefore the photograph of a complete screw gives a true record of the shape as well as the dimensions. The following gives the whether the shadow photograph gave the true shape of the thread. There are two methods of obtaining a photograph of a screw thread—one in which the axis of the screw is at right angles to the beam of light; the other in which the axis of the screw is inclined at an angle which differs from the right angle by the angle of the pitch of the screw. As regards the first detail of the method employed in photographing the screws: On a plate, A, B, C, D (Fig. 2), is a block, E, to which is secured a glass scale, F, which has been carefully etched with lines 1-50in. apart. A piece of spring brass, H G, serves to hold the screw, K K, to be photographed, with its axis parallel to the plate A, B, C, D. The distance of the screw from the plate can be adjusted by means of the screw, I, so that when

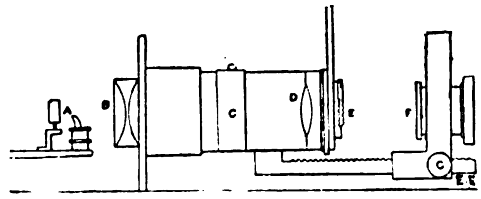

FIG. 3.

the scale is sharply focussed on the screen the shadow of the screw may also be brought into focus. The frame, A, B, C, D (Fig. 2), is adjusted in the same position as an ordinary microscopic slide in a magic-lantern arranged for microscopic work, only I found it desirable to employ a photographic lens of modern design instead of the usual objective. The arrangement is shown in the accompanying diagram (Fig. 3), where A represents the limelight, B the ordinary condenser, C alum-trough to stop the heat rays, D small condensing lens, E screw, in its frame as described in Fig. 2, F photographic lens, G milled-head screw for focussing the lens, F.

APPENDIX II.

Gauges for Verifying the Accuracy of Screws (for Workshop use only). BY A. STROH.

In the gauge represented in Fig. 4 the hole, *a*, is for the external diameter. It should be of exactly the diameter given in the table of sizes for British Association screws. A screw should pass into this hole freely, but without much shake. The hole *b* is the minimum gauge, and the screw should *not* pass into this hole. The difference of diameter between the holes *a* and *b* has not yet been determined by the committee; in the present case it is ·0015in.; *c* is a threaded hole or female gauge in which a screw should just turn freely. The hole *d* is for the diameter of the core, but as it is impossible, without turning down some of the threads of a screw, to pass the core of it into this hole, the gauge, *e*, is provided for gauging the core, or, in other words, the depth of the thread. It consists of a fork, the inner edges of which are shaped so as to enter between the threads of a screw. The correctness of the pitch of a screw is ascertained by placing it in the comb, *f*, and against the back-rest, *g*, and by holding the gauge against the light or a white paper.

It has been found by practice that there is considerable difficulty in making these combs with any degree of accuracy, and also that it would be almost impossible to carry out the above form of gauge for the smaller sizes. It is therefore

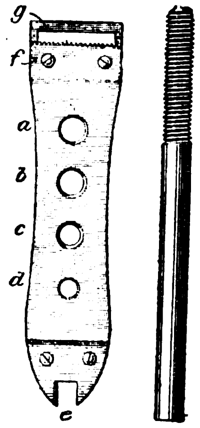

FIG. 4.

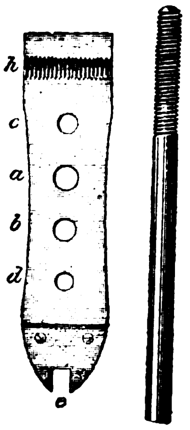

FIG. 5.

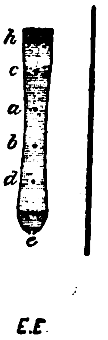

FIG. 6.

suggested that the gauge represented in Fig. 5 has certain advantages over the comb-gauge. With this the half-nut, *h*, is employed for verifying the pitch of screws, instead of the comb. The half-nut can be carried out with greater certainty and ease, and is therefore less costly, and there is no difficulty in making it for the smaller sizes, as shown in Fig. 6. Gauges on the principle of Figs. 5 and 6 have also the advantage of being more compact and stronger for workshop use.

The process of making the half-nut gauge is the following: Two have to be made at one time. When the two steel bars

Digitized by Google

intended for the gauges are filed to shape they are placed together, as shown in sketch (*a* and *b*); a temporary rivet or bolt is put through the hole, *c*, and the ends intended to receive the half-nut device are clamped together as shown. A hole of the diameter of the core is then drilled across the two bars at *d*, so that each bar receives one half of it. The clamp is then unscrewed, the bars are slightly separated, the tap is inserted between them, and the clamp screw tightened again gently. Of course now the two steel bars cannot meet, being prevented by the insertion of the tap. But the smooth end of the tap is

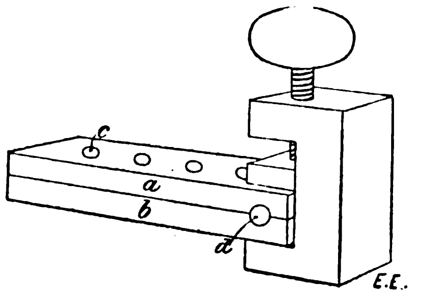

FIG. 7.

now fixed in a chuck on a lathe, and is rotated forwards and backwards, while the clamp screw is tightened from time to time. This is carried on till the threads forming the half-nuts are complete. It is only necessary towards the end of the operation to separate the bars once or twice for the purpose of removing the bur which is raised by the operation.

APPENDIX III.

Mr. Foster informed the committee that in the experience of his firm the limits given in Table II. were found to be convenient for all screws connecting ordinary pieces of mechanism.

APPENDIX IV.

Tests of British Association Screws by Hervé Diameters.

Of the measurements given in Table III. all, excepting the No. 8 steel and No. 11 brass screws, were made with a gauge of which the zero was out of adjustment. The measures to be reduced by ·0002 in the first nine columns. These measurements were made to ascertain within what limits a screw maker can work, not as chausson screws with their theoretical diameters. It seems that 1·2in. below the full diameter is all that is required for brass screws Nos. 0 to 11, and that the same is required for all sizes. It is clear that steel screws are more troublesome than brass, but the lot of No. 4 steel examined were probably not made with sufficient care. The margins are:

1·2	1·0	·9	1·1	·9	1·8	·8	1·2	1·0	1·2	·9
	(1·6)		(3·2)		(3·0)		(2·1)			(1·5)

The figures in brackets in each case include the screws, even those that are clearly too small to pass. The No. 11 brass screws were a lot that Hervé had been asked to make with especial care.

THE ACTION OF METALS AND THEIR SALTS ON THE ORDINARY AND RONTGEN RAYS: A CONTRAST.*

BY J. H. GLADSTONE, F.R.S., AND W. HIBBERT.

The authors, having worked at the action of metals and metallic salts on ordinary light, extended the investigation so as to compare that action with the corresponding transparencies or absorptions for Röntgen rays. The work was principally carried on in the laboratory of the Polytechnic, Regent-street, and photographs of the results were exhibited. The metals experimented on include some with which it is difficult to work, such as lithium, sodium, and potassium.

In regard to the rays of ordinary light, solid metals absorb them completely, and are therefore opaque. If, however, the metals combine with an electro-negative radicle, they lose their power of absorbing light, except a few which show the phenomena of selective absorption. Solutions of salts resemble the crystallised solid in their action on light.

With regard to Röntgen rays, on the contrary, metals exhibit every degree of opacity or transparency, from lithium, which is practically non-absorptive, to such metals as gold and platinum, which are practically opaque, as shown by Barrett and others. The salts of these metals are not transparent, but the metal in them seems to have the same effect on Röntgen rays as in the uncombined condition. This seems to be equally true when the salts are dissolved in water. The order of absorption follows that of atomic weight, not that of density or combining proportion. The absorption of the Röntgen rays by a salt in solution appears to be that of both its constituents added together, plus that of the solvent.

APPLIED ELECTRO-CHEMISTRY.†

BY JAMES SWINBURNE.

LECTURE III.

One of the great difficulties in the commercial use of aluminium and many of its alloys is that of soldering. The problem of soldering aluminium is like that of making motors for ordinary alternating currents. It is solved with a flourish of trumpets every week or two, but somehow commercial aluminium articles are found to be carefully designed not to need solder. One of the difficulties is to get a clean surface of metal exposed to the solder. The principle underlying the use of such fluxes as zinc chloride, rosin, or borax, is that they dissolve the oxide of the metal to be soldered, and of the solder, leaving two clean surfaces to run together. Now, there are few chemicals which will dissolve alumina which will not also vigorously attack the surface of aluminium. There are, however, a few substances available, but some of them need such a high temperature to enable them to dissolve

* Abstract of paper read before the British Association at Liverpool

† Cantor lectures delivered before the Society of Arts.

the alumina that the metal is softened. This prevents such fluxes being used for rolled or stamped aluminium work, as once it is softened the metal loses much of its value. A soldered vessel, for instance, cannot be re-rolled to harden the metal again. One method of getting the solder to stick is to scratch the aluminium under the surface of the solder. There are also several kinds of solder in the market which take on aluminium. This is not enough, however. To make soldering efficient it should not only adher where carefully rubbed on, but should run easily and quickly into joints and crevices, as in sheet-tin, lead, or brass work.

Once the solder has been got to adhere the joint may be quite useless. It is quite easy, for instance, to solder two pieces of aluminium together, so that they will tear through the metal rather than through the solder. Similarly, a screw head may be soldered to sheet aluminium, and when torn off it will take a disc of aluminium with it rather than break the joints. Make these joints and examine them after a few months or even weeks and it will be a very different matter. The solder appears to separate completely from the aluminium, or at any rate it comes off with the slightest force. I believe this does not happen with all samples. It may be due to sodium in the metal, or it may be due to an alloy between the solder and the metal being able to decompose water and thus being corroded. It is possible, for instance, a trace of sodium may help an alloy of aluminium and tin to decompose water. It is a curious thing that a failed soldered joint frequently has the same smell as iron has when acted on by dilute acid. This is generally said to be due to minute traces of hydrocarbon formed from the carbon in the iron, and there is very much less carbon in aluminium. The smell seems to be good evidence of the decomposition of water at the soldered joint. A soldered joint will also sometimes evolve gas very slowly if left in water for some time.

There is another possible explanation which may be brought forward. The two explanations are not antagonistic, and the effects may work together. Aluminium alloys are generally very brittle, or even powdery, if they have a large proportion of aluminium and of the other metal. Thus aluminium with a little copper is a good alloy, and so is copper with a little aluminium, but an alloy of about equal parts is very brittle. Some of the alloys containing large proportions of aluminium and another metal tumble to powder spontaneously in a few weeks. If a metal or alloy is used as a solder, which forms with aluminium in any proportion a brittle or unstable alloy, the probability is the joint will go; for if you pass from the solder to the aluminium you must pass through strata of solder containing more and more aluminium until you are in pure aluminium, and therefore you must pass through a stratum of unstable alloy. This stratum must completely separate the solder from the aluminium, and if it is brittle, or if it spontaneously falls to powder in course of time, the joint must be bad. The obvious cure here is to use a solder that already contains more aluminium than the unstable alloys. Various solders of this sort are in the market.

As regards the uses of aluminium and its alloys enough has been written in the various technical journals. As already suggested, the pure rolled or drawn metal may come into much more extended use when it is supplied free from impurities, such as sodium and silicon. There are other uses than mechanical to which aluminium may be largely applied in the near future. Its great affinity for oxygen, which is its worst characteristic in mechanical work, is its merit in chemical and metallurgical applications. A little aluminium greatly improves many cast metals. It may be that the metals contain dissolved oxide. Copper, for instance, is apt to contain dissolved oxide, which deteriorates it, and is stirred with a green pole before running off. [It was a Cambridge undergraduate who asked his coach if a blue pole would do as well.] It is quite possible that such traces of oxide are reduced at once by aluminium, and that the alumina is insoluble in the molten metal, and rises out at once.

Aluminium can also be used to replace other metals, as it has a very strong affinity for oxygen, sulphur, and chlorine. Thus Vautin makes chromium by heating aluminium with a salt of that metal. Aluminium heated with sulphide of iron yields pure iron with no trace of carbon, a substance that is not familiar to many. As in such cases the products are not easily volatile, and as the action disengages a great deal of heat, enormous temperatures may be obtained in this way. In this way almost any metal may be obtained, as few have such avidity for oxygen, chlorine, or sulphur.

The amalgam of aluminium, or amalgamated aluminium, can also be used as a reducing agent in organic chemistry. It decomposes water rapidly, and reduces many organic compounds. It was generally thought that water must be present for the reduction to take place. This is probably the remains of the nascent hydrogen notion of reduction. People saw bubbles of hydrogen come off zinc in dilute acid, and they found reduction of reducible salts took place, so they jumped to the conclusion that the reduction was the result of the nascent gas, not merely another effect of the same cause. Wislicenus and Kaufmann have finally shown that the amalgam works without water; absolute alcohol, previously freed from all traces of water by amalgamated aluminium, being used as the solvent. It is a question of price how far aluminium may come in in the organic colour industry.

There is a difficulty about electroplating aluminium. It seems as if it might be possible by using a very high current density, just as sodium can be deposited from caustic. It may also be possible to deposit an aluminium alloy from an aqueous solution, as alumina has great affinity for some metals, incandescing on alloying, just as sodium does when dropped into mercury. Various accounts of processes of plating aluminium from aqueous solutions have appeared, but I, for one, have never seen a decent sample of the results. It is, by another process, quite easy to coat iron or copper with either aluminium or aluminium bronze and to produce a thick and impermeable coating, which is quite permanent. This coating is rough, however, and has to be filed up and polished, and it is difficult to do this without occasionally getting through the coating down to the metal underneath. Such a coating may be very useful for large objects exposed to rough usage or to the weather, as merely sand-papered up or pickled it has a handsome appearance.

The further cheapening of aluminium seems to depend on perfection of detail in manufacture which will be caused by keen competition. Cheaper methods, or rather cheapened methods, of producing pure alumina will gradually be introduced. There has been a good deal of talk recently about making aluminium from the sulphide; but it is difficult to say how far any sulphide process has been reduced to practice. It might give purer aluminium, and take less power. It might also save expense in anodes, as at present the anodes are burned just as much as if they were used for reducing alumina in a furnace. The use of sodium for replacing aluminium seems quite a thing of the past. There seems much more chance of aluminium being obtained by furnaces without electrical aid. The Cowles furnace really seems to work by temperature alone. The heats of combination do not necessarily settle whether an oxide will be reduced by carbon or not. It may be that the very high temperature is necessarily only to bring the carbon and alumina into contact. Either the alumina may melt, or the carbon may volatilise. A solution of alumina in a haloid salt is not easily reduced by carbon, however.

The Electrolysis of Fused Salt.

The manufacture of sodium and chlorine, or sodium and bleaching powder, from fused salt direct seems so absurdly simple and easy, that it is a very tempting problem; and if there were not very much more serious difficulties than appear at first sight, such a process as the simple electrolysis of melted salt would very soon oust all others. If a simple method could be devised, sodium could be made at a few pounds per ton. It would be used in very large quantities for the reduction of aluminium, and for replacing iron in the making of cyanides for gold extraction. It would doubtless also be used in innumerable other processes where a cheap and powerful reducing agent could be employed. All this is, however, a small matter; caustic and carbonate would be made from the metal. Instead of a ton of caustic soda, a papermaker would buy 11½cwt. of sodium, which he would convert into hydrate by treating with water. At present we need hardly trouble ourselves about means of treating sodium with water by the ton. It could, of course, be done. The hydrogen might or might not be utilised, and in some cases it might be worth while to get electrical energy by using the sodium in cells. This is unlikely, however; and we are not yet sufficiently near the economical manufacture of sodium to discuss its uses at length.

The difficulties in the way of the direct electrolysis of salt are enormous. In the first place, it must be fused. If it is heated by a furnace, it must be in a suitable vessel. Most kinds of stoneware and earthenware are attacked by fused salt, and are also likely to crack. Iron is the most promising material, but in time it will probably oxidise and scale away. The cost of thick cast-iron pots, something like those used in finishing caustic, might not be excessive. It might be possible to heat the salt by the current that electrolyses it. With a given fall of potential spent on the resistance of the electrolyte, it is easier to keep a large vat hot than a small one, so this method can only be used economically on a large scale. The containing vessel may then be practically solidified salt.

(To be continued.)

Simla.—According to *Indian Engineering*, very sanguine expectations are expressed of having an electric installation in Simla. A great many enquiries have been made by contractors, but only two have been left in—Kilburn and Co, of Calcutta, and Crawford, of Bombay. An attempt will be made to get the power from the Sutlej, a distance of about 15 miles from Simla. The estimate of the expense has been lately considerably lowered, and the Municipality expect tenders to be low enough to permit of at least one offer being considered and accepted. The time for tendering had not elapsed at the time the mail left.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Bucharest.—Tenders will be received at the Mairie, Bucharest, on November 16 for two stand-by steam-engines for a water-power electric generating station at Grozavesti.

Brussels.—Among the contracts for the supply of stores to the Belgian State Railways, tenders for which are receivable at the Brussels Bourse on October 21, is lot 110, consisting of various sizes of electric light carbons.

Wolverhampton.—Tenders are required for an electric lighting heating and cooking plant for the Victoria Hotel, Wolverhampton. Specification may be seen on application to Mr. Thomas J. Barnett, secretary, 25, Darlington-street, Wolverhampton.

London.—Tenders will be received on October 26 for the supply of red fir telegraph poles for the Postmaster-General. Also for creosoting the poles. Particulars and forms of tender are obtainable from Mr. C. E. Stuart, controller of stores, General Post Office, London, E.C.

Brussels.—Tenders will be received on October 21 for the supply to the Belgian telegraphic service of (1) a quantity of galvanised iron wire, (2) various lengths of cable for riverine, submarine, and land service, and (3) a quantity of bare and insulated copper wire. No details are advertised as to the amounts required, but particulars are obtainable at the Brussels Bourse.

Werl (Germany).—The Local Authorities propose to submit to tender the construction and maintenance of an electric power and lighting generating station, and also an electric tramway from Werl to Wikede, with an eventual extension to Hamm. Further particulars will be obtainable at the Rathhaus, Werl-i.-Westf., Germany. The date for the tenders is November 3.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12½ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Madras.—Tenders are invited for the lighting by electricity of Government House, Madras, including the banqueting-hall and aide-de-camps' bungalow, and also for the lighting of Government House, Guindy, including the military secretary's bungalow. For particulars application must be made to the consulting architect to the Government, Chepank, Madras. Tenders will be opened on November 11, 1896.

Monmouth.—The Corporation require tenders for the following contracts: No. 1, machinery (consisting of turbines, alternators, steam-engines, boilers, electric motors, sewage pumps, etc.); No. 3, cast-iron pumping main; No. 4, electric lighting mains. Tenders are to be in by November 2. All particulars are to be obtained from Messrs. Bramwell and Harris, engineers, 5, Great George-street, Westminster.

Brussels.—Tenders will be received on October 21, at the Bourse, Brussels, for installing the electric light at the Arlon Railway Station, including the offices and works. Particulars are obtainable at the Brussels Bourse. La Société national des chemins de fer vicinaux will receive tenders up to October 28 for the conversion of about 14½ miles of tramway in the suburbs of Charleroi into electric lines on the overhead system. Particulars are obtainable, price 1fr., from the office of the Société, Brussels, rue de la Science 26.

Bradford.—The borough electrical engineer is prepared to receive tenders for the following meters—viz., 117 Aron meters, 86 Frager meters, 24 Edison meters, 21 Oulton and Edmondson meters. A list giving details and capacity of the above meters can be had on application to the Electricity Office, Town Hall, Bradford. Tenders are to be endorsed "Tender for Meters," and to be addressed to the Borough Electrical Engineer, Town Hall, Bradford. All meters are guaranteed to be in good condition and working order.

Madrid.—The Secretary of State for Foreign Affairs has received a despatch from H.M. Chargé d'Affaires at Madrid stating that a free public competition is announced in the *Gaceta de Madrid* of September 4 for the grant of the contract for the construction and establishment of three submarine cables to join the islands of Luzon, Panay, Negros y Cebu, in the Philippine Archipelago. Tenders must be lodged within 90 days of the publication of the conditions at the Spanish Ministry of the Colonies, accompanied by a deposit of 50,000 pesetas. The particulars received can be seen at the Commercial Department of the Foreign Office between the hours of 11 and 6.

London, W.—The Great Western Railway Company require tenders for the supply from December 1 next to November 30, 1897, of telegraph instruments, telegraph apparatus, copper wire, G.P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, carbons for electric light, telegraph poles, etc. Samples and patterns may be seen at Swindon from 12th to 23rd inst. on application at the office of the Stores Superintendent at Swindon. Specifications, with forms of tender, may be obtained at the offices of the Stores Superintendent at Swindon. Tenders, addressed to Mr. G. K. Mills, secretary, Paddingdon Station, London, and marked outside "Tender for Stores," will be received on or before 26th inst.

Letterkenny (Ireland).—The Commissioners of Public Works, Dublin, invite tenders up to 12 noon on 19th inst. for (1) supply and erection of poles and one telegraph wire from Londonderry to Letterkenny, a distance of 24¾ miles; (2) supply and erection of poles and two wires from Londonderry to Letterkenny, a distance of 24¾ miles; (3) supply and erection of poles and one wire from Tooban to Letterkenny, a distance of 18½ miles; (4) supply and erection of poles and two wires from Tooban to Letterkenny, a distance of 18½ miles (all to be according to Post Office standard specification); and (5) making telephonic communication from Londonderry to Letterkenny. Address, Mr. P. J. Tuohy, secretary, Office of Public Works, Custom House, Dublin.

London, E.C.—Tenders will be received until 10 a.m. on 26th inst. (*a*) for the supply of red fir telegraph poles, to be delivered in London, King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed, for the Postmaster General. The poles to be felled between November 2, 1896, and March 1 1897, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt-sections, from not less than three poles to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender, containing all particulars, may be obtained on application to Mr. Chas. E. Stuart, controller of stores, General Post Office, E C.

London, E.C.—The Shoreditch Vestry require tenders for the erection of an underground transformer sub-station at the intersection of Great Eastern-street and Curtain-road, Shoreditch, E.C., together with stairways, street refuge, and fittings complete. Specification, quantities, and forms of tender can be obtained and the drawings can be seen on and after 12th inst. at the office of the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of a fee of £3. 3s., which will be returned on receipt of a bona fide tender. The contractor whose tender is accepted shall enter into a formal agreement, under seal, with sufficient sureties for the fulfilment of contract. Trade union rate of wages and hours to be observed. Sealed tenders, endorsed "Electricity Supply, Tender for Sub-station," to be sent at or before noon on 19th inst. to Mr. H. Mansfield Robinson, clerk, Town Hall, Old-street, E.C.

RESULTS OF TENDERS.

Hanley.—For the supply of a second engine for the electricity works, for the Town Council, the tender of Messrs. Ferranti and Co., at £3,300, has been accepted.

London, E.—The tender of Mr. Fife, at £4,087. 10s., for the electric lighting of the Guardians' establishments has been accepted by the Mile End Guardian Board.

Worcester.—The Corporation have accepted the tender of Messrs H. G. Keen and Co., of The Avenue, Cross, for removing the gasfittings from the three sunlights in the assembly-room, and wiring the same for the electric light, according to the specification prepared by the electrical engineer, for £34.

Brussels.—The following tenders were received for an installation of the electric light to the Palais des Académies: Bouckaert and Co., Brussels, £370; the Phaeton Company, Brussels, £414; G. Boty, Brussels, £422; the Electrical Manufacturing Company at St. Gilles, £502. There was also one tender which was irregular, and therefore not considered.

Wandsworth.—The tender of the Private Wire and Telephone Installation Company, of 110, Cannon-street, E.C., has been accepted by the Wandsworth and Clapham Guardians for a telephone installation at "Tooting Home," a large building now nearing completion. Telephones are to be fitted in all the departments on each floor, and the wiring is to be on the intercommunication system, and all the instruments are to be magneto-ringing, fitted with Hunning's transmitters.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,895.

Globe Telegraph and Trust Company.—The directors have declared an interim dividend of 1s. 6d. per share on the ordinary shares.

Folkestone.—The Corporation have approved of the electric lighting draft agreement, and it will now be submitted to the Board of Trade.

Colchester.—A letter was read at the Town Council meeting from the ratepayers' association expressing disapproval of the electric lighting scheme.

Globe Telegraph and Trust.—The directors announce interim dividends of 1s. 6d. per share on the ordinary shares, and 3s. per share on the preference shares.

Wells.—A letter was read at the Town Council meeting from the Board of Trade approving of the method by which it was proposed to light the city by electricity.

Bootle.—The Town Council have decided to retain the electric supply, put their powers into force, select a site for the generating station, and obtain expert assistance.

Spanish Electric Railway.—In the *Revista de Obras Publicas* there is a long article (to be continued) by Mr. E. Azarola on the subject of an electric railway from Pamplona to Estella and Logroño.

Digitized by Google

Oriental Telephone and Electric Company, Limited.—The Board announce an interim dividend of 4d. per share.

St. Pancras.—At the meeting of the Vestry a petition was presented from the ratepayers and residents of Longford-street with reference to the better lighting of that street.

Dublin.—The trailer cars have been discontinued for the winter season on the electric trams running between Haddington-road and Dalkey, and the motorcars only are now used.

Llandrindod Wells.—At the Urban District Council meeting the seal of the Council was ordered to be affixed to the agreement with the electric light company for lighting the streets by means of electricity.

Turriff.—The mansion house of Carnoustie has been fitted throughout with electric light generated by turbine power about half a mile from the house, to which it is conveyed by means of overhead wires.

Order Form.—We have received a specimen of a very handy order form, in the shape of a large reply postcard, from the Reliance Lubricating Oil Company, 19 and 20, Water-lane, Great Tower-street, E.C.

Arundel.—It is proposed to form a telephone exchange for the area of Arundel, Chichester, Littlehampton, and Bognor, and meetings have been held and committees appointed to help forward the matter.

Submarine Cable Trust.—A corrected notice is issued stating that the payment by Messrs. Glyn, Mills, and Co. on and after October 15 of £2. 7s. 6d. is on account of the coupon due on that date, and is not the balance.

Dissolution of Partnership.—G. J. S. Lock, H. M. Lock, and E. C. H. Tiffin, electrical engineers and manufacturers of electrical fittings, Berners-street, W., under the style of Moutrie and Co., have dissolved partnership.

Atlas Steamship Company.—The new steamer "Altai," which was recently launched, is to be fitted throughout with electricity, the machinery for which is to be supplied by Messrs. Clarke, Chapman, and Co., Limited.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending October 11 amounted to £1,076, as compared with £1,118 in the corresponding week of the previous year, being a decrease of £42.

Indo-European Telegraph Company, Limited.—The Board have declared an interim dividend for the half-year ended June 30 last at the rate of 5 per cent. per annum, free of income tax, payable on and after November 1.

Fleetwood and District Electric Light and Power Syndicate, Limited.—This Company has been registered, with a capital of £20,000, to carry on at Fleetwood or elsewhere the business of an electric light company in all its branches.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending October 9 were £2,278. 17s. 11d., compared with £1,675. 10s. 1d. for the corresponding period of last year, being an increase of £603. 7s. 10d.

South Shields.—The Town Council have decided to apply to the Local Government Board for their sanction to the borrowing by the Council of the sum of £7,500 for the purpose of providing the additional plant recommended by the electrical engineer.

Electric Free Wiring Syndicate, Limited.—This Company has been registered, with a capital of £1,000 in £1 shares, to carry on business as electricians, mechanical engineers, suppliers of electricity, and manufacturers of and dealers in electrical apparatus.

Johannesburg.—A telegram from the French Bank of South Africa states that the application of the Johannesburg Tramway Company to the Government of the Transvaal to permit the use of electricity in the place of animal traction will be shortly granted.

Blackpool.—A long discussion took place at the Town Council meeting on the Electric Lighting Committee's minutes, as some of the members thought information as to the totals of certain tenders was being withheld, but in the end the minutes were passed.

Brighton.—In spite of the heavy seas during last week's gale, both Volk's electric railway and the Rottingdean electric railway and car escaped practically without damage. A small portion of the earth bank on the Madeira-road was washed away, but this has been repaired.

Calcutta.—An application from Mr. Archibald A. Crawford, agent for the Allgemeine Elektricitats-Gesellschaft, Berlin, for the consent of the Corporation to his application to the Local Government to supply electricity to Calcutta, under Act IX. of 1895, has been complied with.

Standard Time Company, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to acquire any patents, patent rights, etc., relating to improvements in apparatus for the regulation of time, and to acquire or manufacture and deal with telephones, etc.

City and South London Railway.—The returns for the week ended October 11 were £965, compared with £916 for the corresponding period of last year, being an increase of £49. The total receipts for the half-year 1896 were £13,681, compared with £12,774 last year, being an increase of £907.

Keswick.—At the Urban District Council meeting a letter was read from the Keswick Electric Light Company asking the Council to appoint two representatives to meet a like number of the directors on the 10th inst. to discuss matters. It was decided to agree to the request, and Messrs. Wood and Philipson were appointed as the deputation.

Direct United States Cable Company, Limited.—The Board have resolved upon the payment of an interim dividend of 2s. 6d. per share, free of income tax, being at the rate of 2½ per cent. per annum, for the quarter ending September 30.

Beacon Engineering Company, Limited.—This Company has been registered, with a capital of £5,000 in £5 shares, to carry on the businesses of iron and brass founders, mechanical engineers, electrical engineers, etc., in all their respective branches. Registered office: 32, Victoria-street, Manchester.

Coventry Motor Company, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to manufacture and deal in and with automotor cars, carriages, cabs, omnibuses, tramcars, railway coaches, etc., and also to carry on business as electrical and general engineers, machinists, millwrights, etc. Registered office: Conduits-yard, Coventry.

Aerial Torpedo Syndicate, Limited.—This syndicate has been registered, with a capital of £5,000 in £1 shares, to carry on business as manufacturers of and dealers in aerial vessels of every description, and to acquire and turn to account any patents, patent rights, etc., relating thereto, as mechanical engineers, etc. Registered office: 5 and 6, Great Winchester-street, E.C.

Bangor.—A long and final discussion took place at the special meeting of the Town Council on the question of applying for a provisional order, and in the end it was decided that the Council should apply at the next parliamentary session for a provisional order to enable them to supply electricity within the borough of Bangor and such parts of the parishes of Pentir and Llandegai as might be necessary.

Stretford.—On the minutes of the General Purposes Committee being read at the District Council meeting, the Clerk said the Council had given the sub-committee power to deal with the matter of electric lighting. The sub-committee had retained the services of Mr. F. Bennett, engineer, who would prepare a short detailed scheme, and a report would be presented to the Council at a later date.

Bury St. Edmunds.—At a meeting of the Town Council Mr. Turner (chairman of the Electric Lighting Committee) moved that in order to provide a sliding scale of charges for electricity (as charged in some other towns), if found to be advisable, it be recommended the maximum charge of 8d. per unit instead of 6d. be inserted in the provisional order. Mr. Cornish seconded the motion, which was adopted.

Madras.—At the instance of the Government of India the Madras Government has called upon the agent and manager of the Madras Railway to furnish it with a report showing how the system of electrical communication in trains between passengers and guards and drivers, in use upon the line, has worked, and whether the system is now sufficiently perfect to justify its general adoption on other lines of railway in India.

The Motorcar.—Motor cycles are among the latest productions at Coventry. These will be placed upon the market at the beginning of next month. The London Road-Car Company, whose rolling-stock now totals 900 vehicles, intend to give motor-cars a trial when the law permits. Coventry accordingly hopes to have an opportunity of supplying a considerable number of cars for the omnibus trade in the near future.

Monmouth.—At the Town Council meeting, the Mayor, in reply to questions, stated that about a fortnight previous he had written to Messrs. Bramwell and Harris asking when they would be ready with the specifications for tendering, and they replied that they would be ready in about three weeks from then, so that he expected to hear from them shortly. We give further particulars under the heading of "Contracts Open."

Wimbledon.—It was stated at the Urban District Council meeting that a letter had been received from Mr. Morse, solicitor to the County of London and Brush Provincial Electric Lighting Company, indicating their intention of applying for a provisional order. The clerk was directed to acknowledge the communication, and state that as the Council had themselves decided to apply for a provisional order they could not consent to the company doing so.

Exeter.—The electric light station continues to work favourably, and there is an increasing demand for the light. By hurrying on the new machinery it is hoped they would be able to give an all night supply next month. The committee are considering the advisability of laying down plant if there is sufficient demand for supplying motor power. There has been a certain demand, but not sufficiently definite at present to justify the committee in asking the Council for a loan of £3,000.

Explosion on a Telegraph Ship.—The Telegraph Construction and Maintenance Company's steamer "Scotia," bound from London to Vigo, put back to Plymouth a few days ago, and reported that at four o'clock on Thursday morning in last week one of the officers went into the forepeak with a naked light, when an explosion of corrosive paint occurred, both sides of the bow being blown out and six men injured. The watertight bulkhead alone prevented the ship from sinking. The accident occurred south of Ushant.

Brazilian Submarine Telegraph Company, Limited.—The accounts for the year ending June 30 last, subject to audit, show a profit sufficient to enable the directors to recommend a final dividend of 3s. per share, making with previous distributions a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share, both free of income-tax, which together will amount to £32,500, leaving a balance of £31,060, of which sum £20,000 has been placed to the reserve fund and £11,060 carred forward.

Digitized by Google

New Companies and Electricity.—Among the new companies registered and which take power to manufacture and supply electric current and appliances, telegraph and telephone works, etc , are Middlemore and Lamplough, Limited, Lyons Brewery and Malting Company, Limited, Lake George Mines, Limited, Brock's Goldfields of the Northern Territories of Australia, Limited, the Golden Link Consolidated Gold Mines, Limited, and the Manighatta Company, Limited.

The Electric Tramway at Niagara.—The Buffalo and Niagara Falls electric railway operates a double tracked road between Buffalo and Niagara Falls, 15 miles. Operation was commenced September 20, 1895, and the following results cover the period to June 30, 1896, being nine and one-third months: gross earnings, £14,700; operating expenses, £9,990; net earnings, £4,710; interest on bonds amounted to £5,560; and taxes, £320—total, £5,880, leaving a deficit balance for year of £1,170.

Ipswich.—The Corporation having consulted Prof. Kennedy as to the cost of two schemes of electric lighting which they submitted, he has reported that one would cost £30,000 and the other £42,000. The Council have instructed the Electric Lighting Committee to issue the necessary notices and to take all necessary steps to enable the Council to apply for a provisional order under the Electric Lighting Acts in the next session of Parliament, on the line of the area (*d*) referred to in the committee's report. This is the larger scheme.

Llanelly.—The Highway Committee having given Mr. Howell permission to erect overhead wires temporarily to supply the arc lamps he has put up in the New Dock-road as an experiment, Mr. Griffiths raised an objection at the meeting of the Council, and said they had already refused permission to the Old Lodge Company to lay their electric light wires overhead. He moved an amendment that Mr. Howell be instructed to lay his wires underground, but it was explained that the permission was only temporary, and the amendment was lost.

Chester.—The Town Council have authorised the Improvement Committee and the Town Hall Committee to have the public market and annexe and the town hall respectively wired and fitted up for lighting by electric light under the supervision of Prof. Kennedy and the city surveyor. The Town Clerk (Mr. S. Smith) said the tenders for the lighting of the town hall ranged from £473 to £772, exclusive of the cost of bringing the service into the building, which was estimated at £30. A resolution was carried sanctioning the lighting of the library also.

Cork.—At the meeting of the Public Works Committee, a discussion took place with reference to the electric tramway scheme, and arising out of this, the town clerk (Mr. A. McCarthy) stated that Mr. Murphy had asked him if they could get any part of the corn market grounds upon which to erect a building for the purpose of keeping the elecric dynamo there. The corn market ground was one of the sites recommended, and he (the town clerk) thought the back of it would be a most suitable place for such a purpose if the trustees would be agreeable to the suggestion.

Bristol.—The Sanitary Committee have approved the estimate for the half-year ending March 25, 1897. The cost of electric lighting in public streets is set down at £2,100; last year for the same period it was £2,380. The electric appliances for the Eastville line are being provided as rapidly as possible. The standards and arms are all fixed. The overhead wire has been carried along the track for about half the distance, and the plant necessary to generate additional electricity to serve the newly-laid line is being fixed at the power station at St. George. The Ashton-gate new section is becoming popular.

Tunbridge Wells.—The Lighting Committee reported at the meeting of the Town Council that they had decided to take expert opinion as to the increase of the assessment on the electric light works. Application to extend the lighting mains in Boyne-park and Molyneux-park were acceded to on the usual agreement. The question of utilising the open-air bath in connection with condensing plant was abandoned, the surveyor reporting that the cost of laying a pipe would be £500. It was decided to supply current for motive purposes and motorcars for 3d. per unit. It was decided to give a constant service as soon as the steam-pipes are completed.

Wakefield.—At a recent City Council meeting Alderman Sherwood, chairman of the Electric Lighting Committee, in moving the adoption of the minutes, stated that everything in connection with the electric lighting works was progressing very satisfactorily. He also stated that the City Council had practically agreed with the West Riding County Council for supplying the electric light to their offices now in course of erection. He believed the city would without doubt have the electric light on August 1 next. The price of it would be 6d. per unit, with a rebate to 4d. The Council appeared to regard the statement as very satisfactory.

Burnley.—At the meeting of the Town Council, Councillor Macfarlane said the electric cable to Bank Hall had been carried from under the footpath up the side of the wall and then taken through. It had simply been covered with an iron plate, which had not been properly secured, and one portion of the cable was left exposed. He had seen lots of children playing about there, and he thought it was dangerous to leave a cable in that way. Councillor Bibby said the electrical engineer assured the committee that there was no danger whatever to anyone touching the cable. If there was any defect in the fastening of the plate that would be remedied.

Sowerby Bridge.—A committee has been appointed by the District Council, consisting of Messrs. Wrigley, Wilson, Joseph Greenwood, Lodge, and Sutcliffe, to consider the feasibility or otherwise of providing electric light for the gasworks, the District Council offices, and the public baths. We understand that at these three departments, at the present time, a total of 1,250,000ft. of gas is consumed annually. The electric light, some of the members contend, could be introduced at less cost, especially as as both the gasworks and the baths there are appliances that could be utilised to provide the motive power required for the running of the electric plant laid down.

Bolton.—At a meeting of the General Purposes Committee, matters relating to the extension of tram traction outside the borough and other subjects were discussed at length. The town clerk was instructed to communicate with the districts of Horwich, Tonge, Little Hulton, Over Hulton, and Deane with respect to the extension of tramways to their districts The town clerk was instructed to prepare and give notice of a Bill, to be promoted by the Corporation, to enable the Corporation to work the Bolton and suburban tramways; to authorise the extension of the tramways; and to authorise the supply of electricity for tramways and other purposes outside the borough, etc.

Waterloo-with-Seaforth. — The plan for a new generating station for the Liverpool and District Lighting Company, Limited, on the west side of Brighton-road, Waterloo, was disapproved at the Urban District Council meeting, as the building was shown to be brought forward beyond the front main wall of the house or building on the west side. Mr. Peters pointed out that other buildings in the same street had been approved. Mr. Watts hoped the chairman would pay great attention to that matter. The Chairman said he had the pleasure of sitting on that committee, and could assure him the plans were not gone through without them receiving the greatest consideration from all concerned.

Newmarket.—A special meeting of the Urban District Council has been held to consider a motion that the Council apply to the Board of Trade for a license or provisional order authorising the Council to supply electricity for public and private purposes within the district. The resolution was moved by Mr. Westrope and seconded by Mr. Segrott. Mr. Rodrigo moved as an amendment that the question be adjourned for four weeks, the object being to allow a public meeting being called. The discussion was being continued by the vice-chairman when a member interrupted, and, on being called to order by the chairman, said when a man got up and told lies he must interrupt. As he refused to withdraw this expression the proceedings were suspended, and the meeting adjourned for a fortnight.

Paisley.—The Electric Lighting Committee have had under consideration the following places as sites for the central station in connection with the introduction of the electric light: Carlile's Mill (a piece of ground to the east of Auchentorlie House), Kirkwood, Baird, and Co.'s works at Blackhall, and Morrison's property in Dyer's-wynd. Mr. Teague, the resident engineer, has been instructed to prepare a rough outline of a scheme for a station on each of the sites in Blackhall and Seedhill roads. The committee have also considered the propriety of providing a storage battery for the George A. Clark Town Hall, which would afterwards be available for the central station, but nothing definite was decided on. Mr. Teague informed the committee that the cost of the battery would be about £400.

Southport.—The electrical engineer (Mr. Charles D. Taite) has prepared a report relating to the Corporation electricity works. He states that the capacity of the machinery at present installed is 375 units, but as sufficient plant is held in reserve to take the place of the set utilised in case of accident, the working capacity of the works must be taken as being equal to an output of 250 units per hour. He estimates that by March 31 next the present available plant will be practically fully loaded, rendering additional plant for the following winter a necessity. To meet the increased demand anticipated, a 300-unit alternator and engine to correspond will be required, making the full capacity of the station 675 units. The cost of this new alternator, with necessary additions, he estimates at £12,000, making a total expended capital of £58,882.

Maidenhead.—At the Town Council meeting Councillor Wilton moved, in acordance with notice, "That the Lighting Committee be requested to confer with the town clerk as to the position of the Council in the matter of public lighting, with the view to the undertaking themselves to supply gas for the public lighting." Councillor Wilton gave statistics of the cost to the town of public lighting during the past three years, and spoke in favour of the Council taking the matter into their own hands. On the suggestion of Councillor Gardner, the speaker agreed to withdraw the word "gas" so that the question of lighting by other means might be considered. Councillor Gardner seconded. Councillor Good considered that the lighting of the town should be by means of electric light, and, after some discussion, the motion as altered was carried.

Catalogues.—We have received from Messrs. Wilhelm and Co, 132, Wool Exchange, Coleman-street, London, E.C., a catalogue of electricians' tools, etc., and also an illustrated price-sheet of the arc lamps manufactured by K. Weinert, of Berlin, of which Messrs. Wilhelm are the sole agents. These lamps seem to have one strong feature in their favour, and that is the shortness of the cap. Messrs. Weinert are also sole agents in the United Kingdom for the "Hard" incandescent lamps.—The Jandus Arc Lamp Company send us their latest catalogue, which contains some good illustrations and details and a heap of Press cuttings.—We have also received from Messrs. Peto and Radford a full catalogue of their pocket and portable accumulators, ranging from two to six volts, lanterns and lamps, etc., and a fascintating display of electric jewellery.

Extension of Premises.—Messrs. Royce and Co., of Hulme, Manchester, owing to the increasing demand for their well-

Digitized by Google

known types of dynamos, motors, arc lamps, etc., have found the extension of their workshops necessary, and these extensions, already practically complete so far as building is concerned, are now being equipped with the essential plant. Separate motors will be installed in the new building for driving the various machines, lathes, etc., and likewise in the older portions of the premises where such practice has not already been adopted. The special form of lampholder also manufactured by this firm has won deserved popularity on account of its simplicity of parts and freedom from the usual wooden cord grip, porcelain and metal being the sole elements in its construction. Large numbers of these holders are now being turned out.

Wareham.—At the meeting of the Town Council, the clerk read a letter on the subject of telephonic communication from the local manager at Bournemouth of the National Telephone Company, Limited, from which it appears that Wareham and Poole, and also Corfe and Swanage, are in that area, and that subscribers in these towns could be connected with Bournemouth, Boscombe, etc., at a rental of £10 per annum, providing there was an exchange at these places. The company would open an exchange at Wareham if sufficient support were forthcoming and connect with Bournemouth, and thus with the Post Office wires to nearly all parts of the country. The Town Clerk stated a representative of the company had lately called upon him. He found the company were anxious to connect with Swanage and would possibly include Wareham, although less than the usual number of subscribers were forthcoming. It was resolved that no action in the matter be taken at present.

Shoreditch.—The Vestry have decided to apply for a further loan of £10,000 with which to carry out electric lighting works. Mr. R. F. Ferguson, the resident electrical engineer, has resigned his position in consequence of ill-health. The Vestry have decided to advertise for a permanent electrical engineer for the combined destructor and electricity undertakings, at a commencing salary of £250 per annum. The officer appointed will have to devote the whole of his time to his duties. The London Hydraulic Power Company have written to the Vestry stating that the Vestry's proposals as to charges on mains and services in Shoreditch were without precedent in the operations of the company, and they felt they were not being properly treated by the Vestry. A small fee for each permission to extend the mains and to lay services to cover any expenses to which the Vestry might be put ought, in their opinion, to be sufficient. The letter was referred to the Parliamentary Committee.

Buenos Ayres.—La Capital Tramways Company, Limited, has been registered, with a capital of £100,000 in £1 shares, to enter into an agreement for the acquisition of the tramway known as La Capital, and the benefit of certain tramway concessions granted by the Municipality of Buenos Ayres, in the Argentine Republic, for the construction of tramway lines in the city of Buenos Ayres, and for the using of electric force in regard thereto, together with all or any of the buildings, plant, rolling-stock, stock-in-trade, and other property connected with such undertaking, or acquired in reference to such concessions or any of them; to acquire any other concession or concessions for tramways, railways, or other public works, and to undertake and carry out the same; to carry on the business of an electricity supply company, whether for light, heat, power, or otherwise; as manufacturers of generators, batteries (primary or secondary), lamps, engines, motors, converters, meters, and other electrical appliances.

Monte Video Telephone Company, Limited.—The report of the directors for the year ending July 31, to be presented to the general meeting to be held at Winchester House, E.C., on 22nd inst., states that the accounts show a net profit for the year of £5,727, after providing for all working expenses in Monte Video and London, and after writing off amounts for bad debts and depreciation of office furniture. This amount, added to the sum of £711 brought forward from last year, leaves an available balance of £6,438. During the year a marked improvement has been made in the Company's service by the adoption of a new microphone. The whole outlay of this and other extensive additions to the plant has been charged to working expense. The number of subscribers is gradually increasing, and the general position of the Company is satisfactory. The directors recommend the payment of a dividend of 4 per cent. on the preference share capital (absorbing £5,600), and leaving the sum of £838 to be carried forward.

Sydney.—On August 12 the Hon. J. Young, Secretary for Public Works, moved that the electric tramway from Circular Quay, Sydney, to the Redfern railway station, and along Harris-street to the intersection of John-street, be carried out. The Minister, in speaking to the motion, said that reports from the Public Works Committee go to show that if this tramway be carried out it would probably carry a large number of passengers at a comparatively small expense, and would increase the number of the paying lines. The tramway is estimated to cost £123,000, but some additions may bring it up to £130,000. The annual interest and the estimated total working expenses amount to £32,487 per annum. The annual revenue is estimated at £45,000, leaving an estimated annual profit of £12,513 or over 10 per cent. He quite agreed with the Public Works Committee that the traffic in George-street would not be very much affected by the extension of the railway into the city. After a lengthy discussion the motion was carried on the following division: ayes, 35; noes, 24.

Halifax.—At the meeting of the Town Council the following resolution authorising the promotion of a Tramways Bill was passed by a very large majority: "That the Council do apply to Parliament in the next session for a Bill for all or some of the following purposes; to empower the Corporation to construct, lay down, and maintain tramways in the following streets in the borough of Halifax—namely, Church-street, Horton-street, Wards-end, Commercial-street, George-street, Silver-street, Bull-green, King Cross-street, King Cross-road, Commercial-street (north end), New Crown-street, and Gibbet-street. To empower the Corporation to work the said tramways or any portion thereof when constructed. To empower the Corporation to work the said tramways either by animal power or by steam, or electrical, gas, cable, or any other power. To enable the Corporation to make and maintain stations for generating electrical power on lands belonging to the Corporation or on lands to be acquired for that purpose. To empower the Corporation to levy tolls, rates, and charges for the use of the proposed tramways, and for the conveyance of traffic upon the same."

Levenshulme.—At the District Council meeting Mr. Tunaley, in accordance with a notice of motion given at a previous meeting of the Council, moved that that body apply to the Board of Trade for a provisional order authorising them to light the district with electricity. Mr. Coates seconded, and the motion was unanimously adopted. It should be distinctly stated, he said, that although the Council asked for an order it would not necessarily be put into operation—they would not necessarily undertake the work. All they desired was simply to protect the rights of the ratepayers so that they might have full control over anything connected with the work. The minutes of the General Purposes Committee, which were adopted by the Council, contained a statement by the chairman on the result of a conference which had been held between the surrounding authorities with reference to the supplying of the suburbs of Manchester with electricity. It was understood that the discussion and arrangements would be carried further at a forthcoming meeting, and the committee who attended on behalf of the Council were authorised to agree on behalf of the Council to such terms as they might think advisable.

Belfast.—At the meeting of the Harbour Board Mr. Lawther moved, pursuant to notice, "That the minutes of the general committee meeting of April 23, 1895, and May 7, 1895, respectively, confirming the recommendations of the Joint Works and Traffic Committees of April 18, 1895, relative to the supply of electric light to persons requiring it at Queen's Quay, and the minute of July last as to supplying Messrs Harland and Wolff, Limited, with 30 arc lamps of 1,000 c.p. each, at £10 each per annum, be rescinded." This was a matter which had got into a muddle. All the tenants were offered the electric light at the time the installation was made, and among those who accepted it were Messrs. Harland and Wolff. It was afterwards found that it would be a very expensive thing to do, and would practically absorb all the electric power. The Lord Mayor, it was only right to say, had advised the Board to keep their power in reserve for lighting Queen's-road and the Alexandra Dock, and only accepted the lighting for his firm with a view of using up the surplus power. Mr. Lytle said he would formally second the motion, not for the reasons stated by Mr. Lawther, but for the purpose of bringing the Board into order. The motion was passed.

Leeds.—A dispute has been proceeding at Leeds relating to the hours and wages of outdoor workmen employed by the National Telephone Company. The company recently gave their Leeds employés notice that they would in future be required to work 53 hours instead of 50 hours per week. There was, however, no offer of extra payment, and the reason assigned for the change was a desire to bring the working time into uniformity with that worked in London and other places. On the men putting in a plea for no greater addition to the time than two hours, and also for 1s. 6d. extra wages, the company offered 1s. by way of payment for the three hours under the new rule. A temporary settlement of the dispute has accordingly been arrived at, the workmen continuing their employment with the hours raised to 52 per week and the pay increased by the sum of 1s., pending confirmation by the general manager of the company. The same questions which have been agitating the Leeds telephone workers are a matter of concern to their fellows in Bradford, Hull, and Dewsbury. The Corporation accounts for the year ending March 25 last have been abstracted by Mr. Wm. Derry, the city accountant, and from that abstract we gather that the expenditure on electric light for the year has been £2 527.

Stafford.—The Gas and Electricity Committee reported at the Council meeting that, having considered the report of the electrical engineer, they recommended that, commencing with the ensuing quarter, the initial price for the supply of electricity be reduced from 8d. to 7d. per unit for any quantity up to an average maximum demand of 1½ hours per day during the two winter quarters, and three quarters of an hour per day during the two summer quarters; 4d. per unit remaining as the charge for all electricity used above such maximum demand. Alderman W. H. Peach, in moving the consideration of the report, said the series of decreases in the consumption of gas for the past four months had now ceased. Three new consumers of the electric light had been found during the month, who would take altogether something like 158 lamps. In reducing the price of the electric light, the committee believed they would be furthering the interests of that department, and some customers complained that the cost of the current was too high. Since the works were opened nearly a year ago the number of electric light consumers had about doubled, but if the same increase occurred during the next 12 months the committee would be much better able to meet their liabilities than if they adhered to the present charge.

Winchester.—A provisional order having been obtained from the Board of Trade at a cost of £350, which must be put in operation by June next either by a private firm or the Council, the Electric Lighting Committee reported at the Town Council

Digitized by Google

meeting that they had received an offer from Messrs. Edmondson, Limited, of Great George-street, Westminster, to take over the order and carry out the installation. The following terms had been agreed upon: "The firm to repay the Council the cost of the order, make the installation works, etc., at a cost of £15 000, and the Corporation to have the option of taking over the affair by giving 12 months' notice. If this were given within seven years then they could purchase at the cost of the expended capital plus 15 per cent.; if after seven and less than 14 years, plus 10 per cent.; and if after 14 years, plus 5 per cent. The prices to large consumers per unit to range from 8d. to 6d. by sliding scale. All public lighting to be charged 4d. per unit. The Corporation to select the site of the works." The Mayor moved a resolution accepting these terms, and Mr. Stopher having seconded, it was carried. The present system of incandescent gas lamps in the streets will cease with the contract about 18 months hence, so that till then electricity will not be used in the streets. The compulsory area will be decided by the Council in due course.

Withington.—At a special meeting of the Urban Council the clerk (Mr. Roberts) submitted a report of the sub-committee on electric lighting, and it was resolved: "That the Council oppose any application made to supply electricity within the district by any other local authority or private undertaking, and that an application be made by the Council to the Board of Trade, under the Electric Lighting Acts of 1882 and 1888, for a provisional order, to be confirmed in the next session of Parliament, authorising the supply of electricity for public and private purposes within the area of the district of the Council, and any other areas that may be thought desirable." A committee was appointed, consisting of Messrs. Coombs, Blair, Harwood, Norquoy, Raby, Price, Provis, and Swarbrick, to take the necessary steps for obtaining the provisional order. It was further resolved to oppose the granting of a provisional order to the Manchester Carriage and Tramways Company to construct additional tramways in the district. The proceedings of the General Purposes Committee were also confirmed. The committee stated that a letter had been received from Messrs. J. H. Andrews and Butterworth asking if the Council would consent to an application on behalf of the company they represented for a provisional order to lay down tramways in the district, to be worked by electrical traction. The committee resolved that such consent should not be given.

Coseley.—At the District Council meeting, when the question of extending the gas lighting was being discussed, Councillor Wones thought it was quite a mistake to go on lighting the district with gas. All round them they saw districts and towns, even where they had gasworks of their own, introducing electricity for lighting purposes, and where it had been introduced more capital was being asked for for the purposes of extensions He urged the Council to give the matter full and earnest consideration, to take notice of what was being done all through the country, and not to spend money on gas until an estimate for the provision of electricity had been carefully gone into. The Chairman said the question of lighting the district by electricity or gas was not before the meeting. Councillor Rolinson said it was bearing on the question. In his opinion a mining district was the very place in which it would pay to lay an electric cable—in fact, the electrical engineer who was consulted on the matter looked upon Coseley as an ideal district for lighting by electricity. They were told that if they could get 1,000 consumers it would pay, but no one had told them that if they lit the district with gas they would ever make a penny profit. It could be proved that electricity was more economical than gas, and he hoped too much money would not be spent on gas till the electric lighting question had been further considered. On the last occasion they had the worst of the vote but the best of the argument.

Hampstead.—The Clerk read a letter at the Vestry meeting from the agent for the Norwich Union Fire Insurance Society, stating, with reference to the policy for insurance of the electric lighting station, which fell due on September 29, that, in accordance with the instructions from the Fire Offices Committee, the rates on £13,000 for the building and contents, exclusive of dynamos, would be increased from 5s. to 10s. 6d. per cent., making the total annual premium £89. 5s. as against £53. 10s. Mr. Richardson protested against the short notice given by the company. The chairman explained that all the fire insurance companies met recently and agreed to raise the tariff of insurance on all electric lighting stations. The notice was short, but he thought they were bound to draw the cheque. It was decided to draw the cheque for the amount claimed. Upon the suggestion of Mr. Hanhart the letter was again referred to the Finance Committee, with instructions to report on the whole question. Mr. Reed, chairman of the Lighting Committee, referred to the failure of the electric light in Heath-street Chapel the other Sunday evening, and, for the information of the ratepayers, stated that the fault was not in the public supply. Mr. Harper asked when the report of the Lighting Committee on the question of lighting the public thoroughfares with the electric light would be ready. Mr. Reed replied that he hoped to be able to bring up a report in a month's time. In reply to Mr Aitchison, Mr. Reed said that the Vestry had no power to supply electricity in an adjoining parish.

Bradford.—At a meeting of the Town Council, Mr. W. C. Dixon (chairman of the Gas and Electricity Supply Committee) moved the adoption of the minutes of that body. The minutes showed that the committee had entered into the tenancy of premises No. 204, Swan-arcade, with a view to utilising them for the exhibition and sale of electrical appliances in order to encourage the use of electricity within the borough for the purpose of lighting and as a means of motive power. Mr. Dixon said that the committee had decided to lay a new cable up Kirkgate at a cost of £1,400. There were now about six sets of feeders from the electricity station, and until recently the committee had not been able to ascertain how many amperes each set of cables had had to convey, the result being that some of the cables had been very much overloaded, whilst others had not been conveying their full quota of current. An instrument which registered the amount of current conveyed by each cable had recently been procured, and it had been found that the Kirkgate cable, which was constructed to convey 540 amperes, had had 940 amperes forced along it. That meant a great waste of current, and the new cable was being laid in order to avoid that waste. Alderman J. Sheldon said that tradesmen in the centre of the town were much annoyed and inconvenienced by the frequency with which the main streets were taken up for the purpose of laying gas or electricity mains. Mr. Dixon said that the Gas and Electricity Supply Committee were now, wherever possible, laying down conduits, through which the cables could be drawn. By that means much of the digging up of thoroughfares would in the future be avoided. The minutes were adopted.

Wigan.—Alderman Holmes, in moving the confirmation of the Gas and Electric Lighting Committee's proceedings at the meeting of the Borough Council, said he desired to call the attention of the Council particularly to the meetings on September 22 and 23, wherein they would find that the committee recommended to the Council the postponement of the introduction of electric light into the town. That action was taken because the committee felt that at the present time a new burden would very shortly be placed on the ratepayers of the town by the introduction of an additional water supply. In addition to that, the great body of shopkeepers to whom the committee must in future look for the adoption of the electric light, and therefore its financial success to the town, were at the present time in a state of what might be termed depression, or, what they admitted themselves, a state of bad trade. That was doubtless caused in a great measure by one of their principal industries—coal—being in a very depressed state. They all knew the difference in the trade of the town when the coal trade was brisk and when it was the opposite, and no one knew that better perhaps than the shopkeepers. Therefore, if the electric light were to be introduced now, the committee felt that it must of necessity prove—well, for a considerable time—a financial failure. They therefore recommended that for a brief period—not that they had any wish to throw aside altogether the adoption of the electric lighting of the town—they should postpone it until the committee and the Council might see fit to carry it forward. Those were the reasons principally upon which the committee based their conclusions. Mr. Woods seconded the motion, which was carried.

Eccles.—The General Purposes Committee reported at the Town Council meeting that they had received the following letter from the Board of Trade: "I am directed by the Board of Trade to state for the information of the Corporation that although the compulsory work under the order has not been executed within the time limited for that purpose, the order will not lapse until the Board have exercised their power of revocation. With regard to the request of the deputation from the Corporation who attended at these offices on the 7th inst., that the question of the revocation of the order should be deferred beyond the date fixed in the letter of this Department to June 1, I am to state that the Board will be prepared to consider a further postponement at or about the date referred to, but they are not disposed to bind themselves to postpone the question more than a year beyond the time already allowed. I am to add that should any application for a provisional order be made in the meantime by any company which could show that a substantial demand for the supply of electric force existed, and should the Corporation remain unwilling to put in force the power possessed by them under their order, it would devolve upon the Board of Trade to consider whether they would not revoke the existing order and grant an order to the company applying. In no case would the Board take any steps towards the revocation of the present order until the Corporation have had ample opportunity to make representations in the matter." A letter was also read from Mr. W. H. Bruce, of Manchester, stating that he was prepared on behalf of a London company to treat with the Council for the transfer of the order. The basis of such negotiation would be a saving of between £100 and £200 a year in the present cost of street-lighting, payment for the provisional order and the option of the Corporation to purchase the undertaking at any time. The Council decided to defer the whole consideration of the question of electric lighting until the January meeting in order to give any new members who may be returned in November an opportunity of expressing an opinion.

Hove.—The Works and Improvements Committee reported at the Urban District Council meeting that they had considered an application from the Hove Electric Lighting Company, and after an interview with Mr. Crompton, Mr. Reeves (secretary of the company), and Mr. Smith (manager) it was resolved that the Council be recommended to agree to a modification of the agreement with the electric lighting company so as to permit them to supply electric energy at a pressure not exceeding 220 volts at the consumers' terminals in new streets in which electric lines are hereafter laid, and to new consumers in streets in which electric lines are already laid, the modification to be expressed by deed to be prepared at the expense of the company, and due provision being made satisfactory to the committee enabling the Council to protect the interests of existing consumers. In moving the confirmation of the proceedings, Mr. J. Martin pointed out that the pressure under the present agreement was 110 volts, and that the company now wished to supply electric energy at a pressure not exceeding 220 volts. This increased pressure would only affect new

Digitized by Google

customers, and the pressure for present customers would remain at 110, except any of them wished to change, in which case the company would be prepared to meet them liberally. Mr. Henriques did not quite understand how the present customers would be affected by the application of the electric lighting company, and asked the chairman of the committee for further information. It seemed to Mr. Leeney that the company was asking the Council for a favour, and he wanted to know if the Council would get a *quid pro quo*. The electric light was very dear in Hove, and he should have thought the committee would have endeavoured to secure a reduction to something like the price of the light in Brighton. Mr. Martin, replying to Mr. Henriques, said the company would deal liberally with all existing customers who preferred to have the higher voltage, and he had no doubt they would make the exchange themselves free of cost, or make an allowance With regard to the question of benefit to be derived, he informed Mr. Leeney that for the present there would be neither an advantage or a disadvantage, but ultimately there might be an advantage. The Chairman added that the company could not make any exchange of the voltage without the consent of the consumer. There was no difference in the cost.

Rathmines. — At the meeting of the Commissioners Mr. Edmondson moved the following resolution in pursuance of motion: "That before going further with the electric lighting scheme the opinion of Prof. Kennedy be obtained, and that the Electric Lighting Committee be instructed to take the legal steps in the matter." He said as they were about to spend £40,000 on the electric lighting of the township, they ought to go very carefully and cautiously in the matter. They had already got the opinion of Mr. Hammond, a gentleman against whom he did not wish to say a word, but, having regard to the large amount of money to be expended, it would be well to have a second opinion. He had been investigating the matter recently, and he had found that the most economic results in the way of electric lighting had been achieved in Edinburgh, where Prof. Kennedy was the specialist. He had also carried out electric lighting works in other parts of Scotland and England. He (Mr. Edmondson) would, however, be prepared to modify his resolution by not naming an engineer, but leaving that matter in the hands of the Board. Mr. Hewson seconded the motion and said Prof Kennedy seemed to have a record for cheapness and economy. The Chairman pointed out that the words of the resolution, "before going further with the electric lighting scheme," were not correct, as they had no scheme at present. They obtained a provisional order, but they had not settled on any scheme up to the present, and the matter was still in the hands of the special committee. Mr. Edmondson said they had got a preliminary advice from Mr. Hammond, and they had paid him £50 for that advice. Mr. Bolton did not at all agree with Mr. Edmondson's resolution, and considered it was very little short of bad taste for a member without consulting the committee to propose the name of a gentleman at that Board. Mr. Booth, as chairman of the Electric Lighting Committee, said they had as yet prepared no report; under the circumstances the resolution was a little premature. Mr. Hodgson thought they ought to be all deeply obliged to Mr. Edmondson for bringing the matter forward. Having regard to the fact that such a large sum as stated was to be expended, he thought a second opinion would be most valuable for the special committee to have before going further with the matter. Mr. Beckett was also of opinion that Mr. Edmondson should be thanked for his very valuable suggestions and for the way he had investigated the matter. After further discussion, it was agreed that, before any decision should be come to as to an electric lighting scheme, a second opinion should be obtained, the person to be selected to be considered at a future meeting of the Board.

Mitchelstown —At the meeting of the Board of Guardians the clerk reported that he had written to the Local Government Board as follows: "Sir,—I am directed by the Board of Guardians and the promoters of this scheme to state that they have had under consideration the enclosed circular of instructions from F. L. Warden-Stevens, Esq., in which it is stated that the cost of a license will be from £50 to £60, and the expenses to be incurred after in obtaining a provisional order will be from £200 to £300. This expenditure, if correct, seems to the Board of Guardians so enormous that it will be, as Mr. Webber states in enclosed letter, a prohibition to the carrying out of the scheme, and the Board will feel most thankful for replies to the following enquiries: The Mitchelstown Waterworks Provisional Order was carried though Parliament involving an expenditure of £5 500 at an outlay of £23—namely, local enquiry. £18; parliamentary agent, £5—all preliminaries being done by the clerk of union, and unless there is anything exceptional in the Lighting Act the Guardians in initiating the scheme were of opinion that a similar outlay or something near it would answer. If the license sought for will be granted, the Board propose lighting the town of Mitchelstown with 40 incandescent electric lamps, the motive power, a turbine wheel worked by water, wheel and water to be provided by the Countess of Kingston, of Mitchelstown Castle, who will make a contract with the Guardians to keep the light going for 22 years from sunset until midnight every night in the year. The Guardians are to supply all the plant and erect it save the turbine wheel and dynamo. The plant is to be the property of the Guardians, but to be kept in working condition by the Countess of Kingston for and during the term of contract for the sum of £70 per annum. The Guardians estimate that £500 will be required for the plant they must provide, and the annual instalment of this loan from the Board of Works for 35 years will be £30 The poundage rate on the area of charge now laid out will be 7d. per £ on a valuation of £3,349. The questions the Board are desirous of having answered: (1) probable expense of obtaining a license, the preliminaries to be done by the clerk of the union; (2) whether after obtaining the license it will be compulsory on the Guardians to obtain a provisional order; (3) whether there is anything exceptional in the way of expense in obtaining a provisional order under the Electric Lighting Act, and having it confirmed by Parliament to that in the case of order obtained two years ago for the Mitchelstown waterworks." The Local Government Board replied that the obtaining of a license under the Electric Lighting Act does not come under the jurisdiction of the Local Government Board—it is the Board of Trade who grant licenses and provisional orders. As regards a loan for the work the Board stated that (1) if under a license the time of repayment must not exceed the unexpired time of the license, and (2) if under a provisional order not more than 15 years for cables and not more than 25 years for other plant. The following notice of motion was given: "That the Guardians, for the purpose of complying with the procedure of the Electric Lighting Act, would, six months hence, consider a proposal to make application to the Local Government Board to grant a provisional order for the electric lighting of Mitchelstown, and that the amended area of charge for the scheme be readopted."

Torquay.—At the last meeting of the Town Council the Electric Lighting Committee recommended that the plans, general conditions, and specification of the works connected with the erection of municipal electricity works be approved, and advertisements issued inviting tenders for the supply and erection of the plant in accordance therewith. Alderman Kerswill formally moved the adoption of the recommendation. Alderman Mortimer, seconding, rejoiced to know that at last they were about to seriously take the scheme in hand. He had not the slightest doubt but that in the course of a year or two it would be a paying concern. He did not profess to be able to go minutely into the specification, but he had every confidence in the committee, and felt sure that in the hands of their able engineer everything would be carried through in a thoroughly able and up-to-date manner. Dr. Bunting showed that he had gone carefully through the specification, several details of which he criticised. He wished he could feel as certain as Mr. Mortimer that it would be a paying concern. Still, now the scheme was decided upon he should do his best for it, although he had not approved of it. Mr. Rockhey was glad to find that they had so able a critic as Dr. Bunting had proved himself. He remembered when they were discussing the electric lighting question it was suggested that they should proceed step by step in the carrying out of the scheme, and that the work should be carried out in a tentative way, and not the whole scheme at once. During the last two or three weeks he had been with a gentleman who was chairman of an electric lighting committee in a Midland town, and he strongly advised that Torquay should not go in for arc lamps for street lighting. These lamps were most expensive, and were found to draw very largely on their resources and cause a deficit on the annual working. The scheme provided for 70 arc lamps in Torquay streets. They should take warning by the mistakes of other places, and be advised that they make further enquiries about the matter. Alderman Harrison pointed out that no valid argument had been used against arc lamps, which were in general use everywhere. He had seen a great many of them, and they gave an excellent light. He did not see why they should hesitate about adopting the recommendation of their engineer, who must be fully aware of everything bearing on the scheme. The scheme had been thoroughly thrashed out, and every improvement had been adopted by the engineer. If they were going to have the electric light, let them have it and make the best of it. No good could result from referring back the question to the committee. Alderman Kerswell thought the arc lamps spoken of by Mr. Rockhey must be out of date. Mr. Smerdon said the earliest arc lamps used required almost daily attention, whereas those now used could burn for 140 hours without being attended to. Mr. Butland did not think they could do other than make enquiries, and the scheme would not suffer by a week's delay. Mr. Rockhey said Derby was the town he alluded to, and he believed the works there were of recent construction. The great want, apparently, was a good lamp. There was no lamp which answered the requirements, and the Derby committee was constantly going to their Council for extra sums to improve the lighting. Mr. Garrett suggested, and it was agreed, to insert a clause in the conditions giving the Council the right to make any alteration in the street-lighting. The motion was carried *nem. con.*

PROVISIONAL PATENTS, 1896.

OCTOBER 5.

22000. **Improvements in arc lamps employed in electric lighting.** John Henry Wheat and Arthur Wheat, 67, Blue Bell-hill, Nottingham.

22043. **Improved means applicable for use in working electric railways provided with underground conductors.** Adolf Hecker, 191, Fleet-street, London.

22046. **Improvements in electric switches.** Rookes Evelyn Bell Crompton and Edmund Arthur Norman Pochin, Arc Works, Chelmsford.

22061. **Converting direct electric currents into alternating currents.** David Cook, 30, Lancaster-park, Richmond, Surrey.

Digitized by Google

22069. **Improvements in electric accumulators or storage batteries.** David Young, 11, Southampton-buildings, Chancery-lane, London (La Société Anonyme Accumulateur Eclair, Belgium)

22076. **Electric current director system for saving telephone and telegraph lines.** John Symons Endacott Ellis, 108, Pitt street Sydney, New South Wales. (Complete specification.)

OCTOBER 6.

22093. **Improvements in and connected with dynamos or electric generators, more especially to small machines where permanent magnets are used** James Henry Ward and Meyer Hart Goldstone, York street Electric Works, C-on-M., Manchester.

22102. **An electric lighting device for oil lamps** Hugh Donald Fitzpatrick, 70, Wellington-street. Glasgow. (Julius Eckel and Albert Glinicke, Germany.) (Complete specification.)

22127. **Improvements in electric locomotives** Henry Harris Lake, 45, Southampton-buildings Chancery-lane, London. (Louis Warfield United States) (Complete specification.)

22129. **Improvements in methods or processes for electro-thermally treating materials for the manufacture of calcium carbide and the reduction of metals from their oxides or other compounds.** Hudson Maxim, 45, Southampton-buildings, Chancery lane, London.

22144 **Improvements in electric or other motor trucks** The British Thomson-Houston Company, Limited 70, Chancery-lane, London. (Norman C. Bassett, United States) (Complete specification.)

22146 **Improvements relating to electric light and power circuits.** Edward Wingfield Bowles, 6, Bream's-buildings, Chancery lane, London.

22156 **A new or improved duplex electric switch** Philip F. W. Simon, 28, Southampton buildings, Chancery-lane, London. (Friederich Wilhelm Busch, Germany) (Complete specification.)

22167 **Improvements in or connected with electric incandescent lamps.** Cornelis Boudewijnse, 6, Lord-street, Liverpool.

22173 **Improvements in or relating to telephonic apparatus.** Philipp Johann Böse, 18 Buckingham street, Strand, London. (Complete specification)

OCTOBER 7.

22219. **A portable automatically-driven phonograph and graphophone suitable for commercial, domestic, and general use.** Ernest George Miles and Alfred William Turner, Cobden-buildings, Corporation-street, Birmingham.

22226. **An improved automatic electrical cut-out.** Henry John Wagg, 15, Great George street, Westminster, London.

OCTOBER 8.

22269. **An improvement in telephone switches (automatic).** William Wyld, 3, Clifton-street, Blackpool.

22282. **Improvements in ceiling roses for electric lamps** Christopher Thomas Briscoe and George Hedley Shaw, Penny Bank-chambers, Halifax.

22326 **Improvements in electric apparatus for lighting and extinguishing gas jets.** Gottfried Ferdinand Krieger, 22, Southampton-buildings, Chancery-lane, London.

22333 **A method of exciting synchronous or asynchronous dynamo-electric machines or motors working with alternating currents of constant potential.** John Imray, 28. Southampton-buildings, Chancery-lane. London. (La Société Anonyme pour la transmission de la force par l'electricité, France.)

22352. **Improvements in electric cables.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

22353. **Improvements in apparatus for completing interrupting, diverting, and controlling electric currents.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

22360. **An improved automatic telephonic exchange system** Salomon Berditschewsky-Apostoloff, 53, Chancery lane, London.

OCTOBER 9.

22402 **Improvements in switches for electric currents** William Robert Rawlings and John Joseph Rawlings, 82 Gloucester-road, South Kensington, London. (Complete specification.)

22416. **Improvements in and relating to the supports or holders of electric incandescent lamps.** Edward Prentice, 433, Strand, London.

22423 **An improved manufacture of electrodes for secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery lane, London.

22442. **Improved means for electrically heating water and other liquids.** Robert E. Loesener, 18, Buckingham-street, Strand, London.

OCTOBER 10.

22464. **Improvements in electric switches.** James Marsden and Mark Pearson, 18, Southampton buildings, Chancery-lane, London.

22465. **Improvements in electric measuring instruments.** Arthur Wright, 111, Gloster-road, Brighton.

22513. **An improvement in telegraph cables and their connections.** James Mark Barr and Charles Edmund Stanley Phillips, 28, Southampton-buildings, Chancery-lane, London.

22520. **Improvements in phonographs.** Philipp von Wouwermans, Carl Kohn, Johann Kohn, and Theodor Fischer, 46, Lincoln's-inn fields, London.

22530. **Improved means for controlling and for effecting combinations in the stops of electro-pneumatic organs.** Arthur George Hill, 372, York-road, Camden-road, London.

22552. **Improvements in apparatus for electrically actuating the stopping mechanism of engines, motive power, or machinery in case of accident or otherwise, in part applicable to other purposes.** George Ernest Murray Stone, 217, Upper Thorpe, Sheffield.

SPECIFICATIONS PUBLISHED.

1894

23825*. **Arc lamps.** Brockie. (Amended.)

1895.

8210*. **Magnetic needles.** Gisborne. (Amended.)

9144 **Electric soldering apparatus.** Binswanger and Ball. (Amended)

15564 **Electric propulsion of vehicles or vessels.** Epstein.

18697 **Electric railways or electric transport.** Lorrain. (Esmond)

18822 **Mounting electric incandescence lamps for orchestral, reading, and like purposes.** Crawshaw and Bevis.

19669. **Secondary battery plates.** Schanschieff.

20828. **Primary electric batteries.** Rowbotham.

20925. **Primary and secondary batteries applicable for use with pocket electric lamps and for other purposes.** Burnet.

1896.

15074. **Electrically-ignited torches, cigar-lighters, or the like.** Hencken and Meyer.

16421 **Regulator for dynamo machines.** Heusch and Brandt.

17643. **Pocket electric lamp for use by surgeons and the like.** Smith and Green.

18273. **Dynamo-electric machines.** Lake. (Lundell and Johnson.)

NOTES.

The Pacific Cable Scheme.—A telegram from Halifax, Nova Scotia, states that the Hon. Alfred G. Jones, formerly Minister of Militia, has accepted his appointment as Pacific Cable Commissioner, and will sail for England at once.

Telephones on the Continent.—The Brussels correspondent of the *Daily News* says recent trials between Antwerp and Berlin have been so far successful that the work of placing the two cities in direct telephonic communication will shortly be proceeded with.

Bad Light.—A lady has written to the *Times* to say that she has a boy at a public school, and that his eyes have gone wrong. An oculist was consulted, and put it down to a combination of small print and bad light, and added that "half the cases brought to his notice of children and young people are of the same class, combined with working in rooms insufficiently or badly lighted. Gas he strongly condemned."

Liverpool Engineering Society.—The opening meeting of the twenty-third session of this society will be held at the Liverpool Royal Institution on the evening of Wednesday, the 28th inst., at eight o'clock, when the president-elect, Mr. S. B. Cottrell, M.I.C.E., M.I.Mech.E., will deliver his inaugural address. The first of the fortnightly meetings is on November 11, and we hope to give a programme of the papers for the session next week.

American Telephones.—The contract of November 1, 1879, between the Western Union and American Bell Telephone Companies covering the use of certain patents will expire November 1, when all the patents embraced in the contract will run out. Under this contract the Western Union has received from the American Bell Telephone Company royalties amounting at one time as high as £120,000 per annum, but of late aggregating less than a quarter of that amount.

Physical Society.—A special general meeting of the Physical Society of London will take place at the rooms of the Chemical Society, Burlington House, at 5 p.m. on Friday, October 30, after which at an ordinary meeting there will be the following papers: (1) "A Satisfactory Method of Measuring Electrolytic Conductivity by Means of Continuous Currents," by Prof. W. Stroud and Mr. J. B. Henderson; (2) "A Telemetrical Spherometer and Focometer," by Prof. W. Stroud; (3) "An Experimental Exhibition," by R. Appleyard.

Telegraph Rates to India.—In a communication to the Liverpool Chamber of Commerce, the Postmaster-General regrets that his representations to the telegraph companies, in favour of a reduction in the rates to India, have been fruitless, in face of the great loss of revenue which would be involved. On the other hand, the companies have, it is stated, made reductions in the charges for telegrams to the Far East, particulars of which are to be announced. The rate for China will be reduced, it is said, from 7s. to 5s. 6d. per word.

Next Week.—Eastern Extension Telegraph Company's meeting is on Wednesday at Winchester House. The Brazilian Submarine Company's meeting is also at Winchester House on the same day. The opening meeting of the Liverpool Engineering Society takes place at Liverpool on the same day. There will be an Electro-Harmonic concert to-day week (October 30). The Physical Society meets on Friday, October 30, at 5 p.m.; particulars of the business are given in another note. There is a visit of the Junior Engineers to the Hotel Cecil on October 31 to inspect the electric lighting there.

Exhibitions.—A meeting has been held at the London Chamber of Commerce in support of the Vasco da Gama and Indian Celebration and Exhibition at Lisbon next year. Sir A. Rollit, M.P., president of the chamber, was in the chair, and many City firms were represented. In reference to the Brussels Exhibition of 1897, the report of the executive commissioner to the British Commission shows that already the minimum area acquired for the British section (3,000 square metres) seems likely to be secured by exhibitors of the first rank. Space in addition to the minimum area can be acquired, if necessity arises, before the end of the year.

Accident.—Dr. G. Danford Thomas has held an inquest at the Holborn Town Hall on the death of William Creighton, aged 36, a working foreman in the employ of Messrs. W. Scott and Co., the contractors engaged in constructing the Holborn Station of the Central London Electric Railway. Creighton was working at the bottom of a pit 80ft. deep. A skip laden with earth had just been raised when the rope broke, and the skip fell upon him and killed him. When the skip was raised the workmen below were told to stand clear, but deceased thought it was up and had resumed work. A verdict of accidental death was returned.

The Telephone Service.—The following is from the *Financial Times*: "The telephone men of Yorkshire are threatening a strike, owing to an inforced increase in working hours on the old standard of pay. The strike, we are told, may possibly assume a national character. On the whole, we receive the news with perfect equanimity. If the telephonists strike we shall be able to save time by the employment of messengers instead of wasting valuable hours by the pretence that the telephone is more expeditious." In Fifeshire they display an inclination to try if they cannot do things better than the combined result of the Government and the Telephone Company's efforts. In our City contemporary's office they apparently merely despair.

New Publication.—We have received the first number of the *Automotor and Horseless Vehicle Journal*. This is, or is to be, "a record and review of applied automatic locomotion." It is to come out monthly from 62, St. Martin's-lane, for the price of 6d. The present issue contains the text of the new Act, some illustrations of motor carriages, a portrait of Sir David Salomons, a great deal about the Paris-Marseilles race, and notes and other matter to make up 35 pages. As there cannot be very much to record and review just at present on the subject of motorcarts in this country, this is not a bad start. The only thing we dislike about our new contemporary is its name. Quite apart from questions of linguistic purity, people who have already got automaton in their memory will not easily say auto-motor, while as for "horseless vehicle," that is a periphrasis which covers, among other things, donkey-carts, bicycles, wheelbarrows, and bath-chairs.

Lightning Flashes.—About a month ago a very curious lightning flash, in which the course of the discharge was a spiral, was described by a correspondent of *Nature*. Mr. Benjamin Davies now writes saying that some years ago he witnessed what was probably a flash of the same kind. "In the early evening of a fine summer day," he says, "while sitting leisurely on a hedge on a comparatively high hill near to Llandyssul, in the county of Cardigan, with an immense area of country within reach of my vision, there appeared slightly above the horizon in the west what seemed to be a perfectly endless flash, almost circular in shape, and exceedingly serrated. There was not a single stray end to be seen, as in Mr. Burch's flash. I heard no thunder, and I knew from the faintness of the

Digitized by Google

spark that it was at a great distance from me. This flash lasted for a longer time than any one I have seen since. I happened to be gazing at the actual spot when the flash occurred, and I saw it well."

Mischief.—At places where they entertain it is just as well to put the switches out of the reach of the public. This week at the Aberdeen Police Court, before Bailie Brown, John Simpson, apprentice cabinetmaker, Esslemont-avenue, was charged with having, while the Patti concert was proceeding in the music hall, on the 12th inst., turned off part of the electric current by which the buildings were lighted, to the danger and annoyance of the audience. He pleaded guilty. From a statement by the procurator-fiscal, Mr. Lamb, it appears that on the night in question accused had been at the hall with a companion. Accused suggested to the latter that he should turn off the light, but this the other lad refused to do, and accused thereupon proceeded himself to put his suggestion into execution by turning one of the electric knobs. The Bailie said the offence was a serious one, especially in a place where there was such a large crowd, and marked his sense of its serious nature by imposing a fine of half-a crown, with the alternative of 24 hours' imprisonment.

The German Association.—At this year's meeting of the German Association, which, unlike the British, includes medicine and surgery as well as natural science within its scope, the president was Prof. H. von Ziemssen. The meeting was at Frankfort-on-the-Main, and among those present at the opening was the Empress Frederick. There was practically no presidential address. In the physics section Prof. Quincke read a paper on rotation in a constant electric field, and there were contributions by Dr. Tuma on Ruhmkorff coils, by Prof. Nernst on contact electricity, and by Prof. Van 't Hoff on slow oxidation. Dr. Traube and Dr. Wiechert had contributions on the arrangement of the elements, and Dr. Karl Schaum on physical isomerism. There was a paper from Dr. Coehn on the electrochemistry of carbon compounds, and Prof. Lenard had a contribution on cathode rays. An immense amount of work was got through, and when it was over there came the visits and excursions, including one to the Darmstadt technical institute.

Motorcarts.—An exhibition of motorcars has been held at the Palais de l'Industrie, in Paris, and among the exhibits were the cars which have been recently run from Paris to Marseilles and back, a distance of over 1,000 miles. These still bear the marks of the journey, but the *Daily News* correspondent says that beyond damaged tyres, which are mostly of solid indiarubber, the distance and high rate of speed do not seem to have affected them. "Reckoning 10 hours to a day's run, the fastest performance was 66 hours for the double journey, accomplished by a phaeton to hold four." The vibration is complained of. As they were all petroleum cars, that is not wonderful. In this country the date for the Motorcar Club's run to Brighton has been again set back from the 24th inst. to Saturday, November 14, the date when the new Act comes into force, and between 30 and 40 motorcars are expected to meet at the London Metropole at 10.30 a.m. for the event. It is understood that the police were—arranged with, but that the Surrey County Council was obstructive up to the last.

Electro-Harmonic Society.—There will be a smoking concert on Friday, October 30, 1896, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock. The following is the programme—Part. I.: violin, piano, and Mustel organ, "Largo" (Handel), Messrs. T. E. Gatehouse, Alfred E. Izard, and H. M. Higgs; song, "The Devout Lover" (M. V. White), Mr. Daniel Price; recitation, Mr. Charles Fry; pianoforte solo, "Tarantella" (Chaminade), Mr. Alfred E. Izard; hand shadows, Mr. David Devant; sacred song, "Ave Maria" (Gounod), Master Willie Gammage; humorous sketch, Mr. Walter Banks. Part II.: violin, piano, and Mustel organ, "Cantique de Noël" (Adam), Messrs. T. E. Gatehouse, Alfred E. Izard, and H. M. Higgs; song, "Molly Carew" (Constance Maud), Mr. Daniel Price; violin solo, "Three Songs Without Words" (Mendelssohn), Mr. T. E. Gatehouse; recitation, Mr. Charles Fry; Mustel organ solos, "Prière et Berceuse" and "Villageoise" (A. Guilmant), Mr. H. M. Higgs; song, "Killarney" (Balfe), Master W. Gammage; humorous sketch, Mr. Walter Banks. The musical directors are Mr. T. E. Gatehouse and Mr. A. E. Izard.

The Morse Alphabet.—The *Daily Telegraph* says: "It is good for the public that telegraph clerks are peculiarly anxious to clear themselves from the accusation of carelessness insinuated against them by the Bishop of Stepney and a 'North London Clergyman.' In addition to the letters of protest already published, a telegraphist writes from Paddington to point out the difficulties under which operators labour. 'Taking a fair average speed of 30 words per minute, we get 900 sounds per minute, or 54,000 per hour. Between each dot and dash there must be a space equal to one dot. Between the letters the space should equal two dots and between words three dots. Working at the above-mentioned speed the duration of each dot would be one-eighteenth of a second, the dash, being equal to three dots, would occupy one-sixth of a second. The difference then between a dot and a dash is equal to one-ninth of a second. This difference is so very slight that if a dot is in the least degree lengthened it would sound like a dash, and of course *vice versâ*. As an example, take the words 'boy' and 'box.' One of the dashes in the letter 'y' having been shortened by one-ninth of a second in duration becomes 'x.' Another example is 'dead' and 'bad,' where by spacing one-ninth of a second instead of one-eighteenth between the 'd' and 'e,' those letters become 'b' ('d' has one dash and two dots, 'e' one dot only, while 'b' has one dash and three dots). By taking the sense of the message many of those errors are avoided, but very frequently the senders, to save a halfpenny or two, cut down the message so that there is no sense in it for the telegraphist's guidance."

Electricity and the Farm.—One of the things that will never be understood is why usually sensible and careful papers should feel at liberty to print any nonsense if it is only stated to have occurred in America. The following is a "Note" in the *Newcastle Daily Chronicle*: "The connection between electricity and agriculture is becoming daily more intimate in the United States. According to the officials of the Washington Patent Office, inventors have turned their attention largely to the adaptation of electricity to farming, and have displayed so much industry and ingenuity that there is now no reason why a farm should not be worked entirely by electricity. Electric ploughs, harrows, drills, carts, reaping and binding machines, and even contrivances for forcing, are at the disposal of the husbandman. Several electric farms, so to speak of them, are already in existence. In the neighbourhood of Chicago power is derived from the river, and in the West a 15-blade plough, which will cut a furrow 6ft. wide, is also actuated by water. The blades revolve, and the plough is pulled across the field by means of a cable passing round the drum of an electric motor on the plough." Surely at Newcastle, if they have never seen a plough, they must have seen a furrow. We think that a plough hauling itself along a wire rope by means of an electric motor might work

Digitized by Google

out a cheaper machine than the present steam-plough, which is hauled along by a moving rope, and all that has been done in the way of experimenting on the effects of the electric light and of earth currents in vegetation has received full attention in these columns. But the enterprising landowner that sends a commission to the States for "electric ploughs, harrows, drills, carts, reaping and binding machines" is likely to be disappointed.

Indiarubber.—It has been stated in the New York *Electrical World* that in America manufacturers and dealers in indiarubber goods are turning their attention to Southern Florida as a possible source of supply of the rubber, the increase in the consumption of which grows at a much quicker rate than the production. At the present time the electrical industries alone demand a greater supply than was used in the world's entire rubber industry a generation ago, and the necessity for new sources of supply is well understood in the trade, though no immediate anxiety is felt. Doubtless there is enough caoutchouc in the world to meet all the demands of the present generation. But the demand is increasing at a rate that is not realised except by the dealers and manufacturers. Of the present supply about two-thirds comes from Brazil. The other third comes from various parts of the tropical and sub-tropical world, and from time to time new fields are opened as the older ones are worked out. The trouble with Florida will probably prove to be, as usual, that the climate of that State is neither one thing nor the other—neither sub-tropical nor temperate. That is to say, that occasionally there are frosts there which are severe enough to affect orange trees.

The Junior Engineers.—The annual general meeting of the Institution of Junior Engineers was held at the Westminster Palace Hotel on Friday last, the retiring chairman, Mr. H. J. Young, presiding. There was a large attendance of members. The council's annual report, which was read by the secretary, Mr. Walter T. Dunn, showed that the total membership was now 454, an increase of 36 on the past year. Mr. A. R. Binnie, M.I.C.E., is the president for the ensuing sixteenth session. Seven meetings had been held for the reading and discussion of papers, and 11 visits to works had been made, at which the average attendance had been nearly 90. The summer meeting in Scotland had been highly successful. The report also contained a copy of the address of congratulation presented to Lord Kelvin, one of the institution's vice-presidents, on his professorial jubilee. Reference was made to the work carried on by Mr. H. Kempster as hon. librarian, and to the special course of lectures on marine-engine design by Mr. H. H. Rounthwaite, and the institution's first conversazione, the appointment of delegates to the Sanitary Congress, and the office fund, were other matters noticed in the report. The officers for the ensuing year were elected as follows: chairman, Mr. H. P. Varley; vice-chairman, Mr. Basil Joy; hon. librarian, Mr. H. Kempster; hon. auditors, Messrs. W. H. D'Ritter and P. Marshall; members of council, Messrs. Adam Hunter, E. Barry, K. Gray, Bertram Joy, A. Anstruther Thomson, G. F. Burtt, E. King, and Walter J. Hunter. The inaugural meeting of the sixteenth session will take place on November 6, when Mr. A. R. Binnie, M.I.C.E., will deliver his presidential address. There will be a visit of the members on Saturday, 31st October, at 3 p.m., to the Hotel Cecil, to inspect the electric lighting, hydraulic, warming, and other engineering features of that establishment.

Lord Rosebery on German Competition.—Lord Rosebery has been eating oysters at Colchester and opening a technical school there. As, in spite of recent events, he is a person who stands a chance of getting his views carried into effect, what he says is important. Lord Rosebery's speech is too long for reproduction here, but he began with a tale of an American: "The other day a young American gentleman came through the technical course in Germany. He was offered a considerable position in that country, but he preferred naturally, being an American, to live in England if possible, if in Europe at all, so he came over to England, and he was at once offered by a large firm a lucrative post. The firm told him, 'Oh, if we had many men like you, employment could be found for all of them; but what happens is this—we have not men possessing the technical and commercial education which is given abroad; we have to take foreigners to fill these posts, and the result is that foreigners learn our business, and go back, very properly and naturally, and practise it at home to our detriment, and as our rivals.'" His Lordship considered this an object lesson worth a ton of argument, and ended by urging an enquiry on the subject. "An exhaustive enquiry would not be long. The facts are all at your fingers' ends. They only need a very small amount of codification and further enquiry. I will take three men, one of whom is present with us to-day [Sir Courtenay Boyle was at Colchester], who can bring such an enquiry to an end in six months without spending £500 of public money. I say that Lord Farrar, Sir Philip Magnus, and Sir Courtenay Boyle could, without the slightest difficulty, produce all the facts bearing on this subject within six months. They have only to examine the consular reports, to obtain reports from leading merchants engaged in foreign trade, and to ask for the opinions of our Chamber of Commerce. If they do this, I will venture to say, without prejudging the case, that they would produce a compact and handy volume that would make all the hair of the public stand on end."

Aerial Navigation.—We have received some illustrations and a description of an "air ship" designed by Mr. C. Tziolkovsky. We need hardly add that the inventor is a Russian. As a large part of the description of the vessel is in Russian, and only a part is translated into French, it has not been so easy for us to follow the matter. The apparatus consists of two essential parts; one, the balloon giving the lifting power, and the other the car containing the motors. The balloon is of the orthodox cigar shape, but iron enters largely into its composition. It is some 220 yards long and 65 yards diameter. On the car a number of gas-engines are placed which are supplied with fuel from the balloon. The exhaust from these is passed out through a pipe, which is led through the balloon before reaching the atmosphere. The heat of this pipe causes the gas to expand, and thus to make up for the quantity abstracted for the engines. A by-pass valve allowing the products of combustion to escape direct into the air affords a means of regulating this heating effect. The inventor places the engines at different parts of the car, so as to get steering and elevating power. The balance of the car is also regulated by a small truck holding ballast. The whole idea seems most feasible if only the figures on the subject would be more in keeping with the desires of the inventor. We notice that the car is to take 70 passengers, and their weight is a comparatively small part (one-seventh) of the total weight. We then calculated the lifting power of the quantity of hydrogen gas said to be contained in the balloon, and do not find it to rise to the occasion. Of course, everything depends on the details in a case of this kind, and we are afraid that the details of the apparatus before us are yet to be successfully overcome. It is a pity that such should be the case, as the balance-sheet in the description shows that a profit of 500 per cent. per annum would accrue to

Digitized by Google

the owner of the aerial omnibus. This is on the assumption of a regular traffic of 7,500 hours per annum. The mean speed is estimated at 25 miles per hour, and the charge per mile at 2½d.

An Electric Street-Sweeper. — The *Scientific American* publishes a large illustration of an electric self-loading car for sweeping up and carrying off the street refuse. The car is 8ft. wide by 25ft. long and 11ft. high. It is carried on two axles, and is fitted with the usual equipment of a trolley car. The brakes and the motor are placed above the wheels. The motor is connected by chain and sprocket gear to the driving wheels and to the brush, the brush making five revolutions to one of the car wheels. The brush runs in a cylindrical case which is open at the top and the bottom, and it is arranged to work both ways, a reversible steel deflector being arranged above the brush. The car consists of an upper platform, in the centre of which is a shelter or cab containing the motor, and a lower closed section, into which the street rubbish is thrown. Its lower floor is formed in parallel sections, which are hinged transversely to the car, and by the operation of a lever can be opened for dumping out the refuse. The broom, which ordinarily is the full width of the car, can be extended to cover nearly the full width of the street if so desired. In operation these cars are used in connection with manual labour, the sweepings of the gutters and sides of the street being thrown toward the centre, where they are picked up by the car, which thus sweeps its own section of the road, and also takes the place of the refuse carts. The car is the invention of A. Jackson Reynolds, of Montreal, who states that when sweeping it travels at the rate of six to eight miles an hour, and that it carries refuse, snow, etc., out of the city at a cost of 10s. per mile. For removing snow a car specially wide and long is constructed, and it is claimed that by running the car continuously during a snowstorm there is no difficulty in keeping a street open. A self-loading car is now being built, which will be one of the largest street cars in the world, being 8½ft. wide and 45ft. in length. It will have a capacity for cleaning 25 miles of street without stopping. We have before referred briefly to this invention, but the details given above have not hitherto been available.

A Western University.—We have received the *Catalogue* of the University of Wisconsin. Few things are more curious than the different ways in which the idea of a university finds expression in different countries. There is the cast-iron system of France, as compared with the German system, just at present so very much admired by all who know little about it. We have our own in England, which, like many English institutions, is unique, and totally and completely different ways of doing things in Scotland and Ireland. In the United States the function of establishing or chartering a university belongs to the State and not to the Federal Government. As there are 45 States, the limit of the centralised system there is fortunately the boundary of the State, and there are universities of all sorts. An English undergrad., for instance, would be tolerably puzzled as to the meaning of a "college" or "hall" at the Wisconsin University at Madison. Wisconsin looks big on the map, but when its population is remembered the long list of instructors and special lecturers, as given by the *Catalogue*, in the mechanics and physics department seems wonderful; but throughout the genius of the American nation is shown by the energy devoted to practical matters. The following relates to laboratory work: "For elementary instruction in the electrical laboratory, the electrical apparatus of the physics department is available. The electrical laboratory is also well supplied with exact scientific and commercial instruments, and is arranged for instruction and investigation. With the additional space and apparatus which is allowed through the generosity of past legislatures, the equipment has been made unusually complete in the lines of continuous current, and single and multiphase alternating current generation and distribution, and commercial electro-chemistry. The dynamos in the laboratory are arranged in a large special room, with a special engine of exceedingly close speed regulation. For use in testing dynamos, all necessary apparatus, including a Brackett cradle dynamometer, is at hand. A photometer-room is well arranged for the commercial comparisons of arc and incandescent lamps, or for scientific investigations."

A Retrospect.—In the course of the Huxley memorial lecture, delivered at Charing Cross Medical School by Prof. Michael Foster, the condition of things in the scientific world when Huxley was a student is compared with that at the present time. As the expression of testimony of a biologist to the educational value of physics, the following remarks of Prof. M. Foster have an importance outside their intrinsic interest: "At the present time the sciences of physics and chemistry have each of them developed into a body of logically co-ordinate truths, furnishing an instrument of peculiar value for the training of the scientific mind. Moreover, the methods of teaching have developed in no less a degree, so that in the laboratory the student follows, at a long distance, it is true, but still follows the steps of those who have made the science, and has at least the opportunity of catching something of the spirit of scientific enquiry. In this educational value of these sciences, even more than in the practical utility of a knowledge of the mere facts of the sciences, great as that may be, lies the justification of the authorities when these, desiring to improve the profession by introducing artificial selection into the struggle for existence, insist that all to whom the lives and health of their fellow-men are to be entrusted should have learnt at least something of the sciences in question. In the time of Huxley's studentship both these sciences were in a very different condition. The time, it is true, was one of great awakening. In physics men's minds were busy opening up the hidden powers of electricity; some 10 years before Faraday had made an epoch by discovering induced currents; he and others were still rapidly extending our knowledge, one practical outcome of which was the introduction of the telegraph in 1837. But how great has been the onward sweep in electric science since then; how great the advance in all branches of physics! To realise the great gap which separates the physics of to-day from the physics of then one has only to call to mind that the world had yet to wait some years before Mayer, and Joule, and Helmholtz, and Grove had said their say; in the books which taught young Huxley the laws of physics he found not a word of that great law of the conservation of energy, which like a lamp now guides the feet of every physical enquirer, whatever be the special path along which he treads."

Acetylene Explosion. — The early workers with acetylene always considered it a dangerous gas, especially when under pressure, but it has been supposed lately that the danger was over-estimated. At Paris last Saturday there was an explosion on the slope of Montmartre in a building where for two months Mr. Raoul Pictet, the Geneva chemist, has been manufacturing acetylene. One of the steel tubes, 3ft. long, used for storing the gas, exploded. It was the dinner-hour, and only three workmen were on the premises at the time. The accident caused for some moments a panic in the district, as people

Digitized by Google

thought that a dynamite explosion had occurred, and rushed about the streets seeking to escape from what they regarded as a catastrophe which was to have widespread consequences. When the police entered the Pictet establishment, they found that the whole frontage of the place had been blown out. The headless trunk of one workman, Pierre Pautre, was discovered buried beneath a mass of broken glass and rubbish. Not far away from an intact gasometer was the carbonised corpse of Léon Secret, another person employed by Mr. Pictet. It has been ascertained from the fragments that the tube which exploded, and which was practically full, was returned from Brussels on the 13th inst. along with 74 empty ones. It is suggested that the workman either held a lamp near it or was unscrewing the stopper with such force as to produce heat, but nothing is really known. In another part of the premises were 30 tubes, each containing 26 gallons of acetylene, as also two large reservoirs, one containing 5,000 gallons. It seems difficult to account for the extreme violence of the explosion. It has been suggested that acetylene might explode on detonation even when quite unmixed with air, but it will be noticed that in this case the explosion did not spread. Negative evidence of that kind, however, is not of much account. According to researches on the explosive properties of acetylene by MM. Berthelot and Vieille, communicated to the Paris Academy of Science, in which details were given of experiments carried out with a view of seeing what precautions (if any) are necessary in the preparation, compression, and storage of acetylene for commercial uses, the decomposition of acetylene by a heated wire, by mercury fulminate, or by the electric spark, is not propagated any considerable distance if the gas is under atmospheric pressure. At pressures of two atmospheres and over, however, the decomposition is complete, the explosive pressure produced rising so rapidly with the initial compression, that the effects produced by detonation of the liquefied gas resemble those of ordinary explosives.

Technical Instruction Abroad.—The annual meeting of the Leicester Technical Schools was the occasion of an address delivered by Mr. W. Woodall, M.P., one of the members of the Royal Commission on Technical Education. Mr. Woodall, with certain of his old colleagues, has recently paid an unofficial visit to Wurtemberg and Bavaria. In the course of his speech, Mr. Woodall made some interesting remarks with reference to the Stuttgart Polytechnic and the Schuckert works. At Stuttgart in 1884 the polytechnic had been enlarged at a cost of £75,000, and included departments for chemistry, physics, and architecture. But since that time, in deference to the urgent demand, imposing buildings had been erected for special and separate instruction in electricity, chemistry, and for building. Each of these cost about £50,000 for erection and as much more for equipment. The Industrial Museum was a noble edifice, recently erected at a cost of £200,000, modelled on South Kensington, and completed and furnished admirably. The Stuttgart Electrical Exhibition this year had shown how marvellously in a State that had no coal mines electricity had been made applicable for motive power, for lighting, and cooking, and new industries of every kind were being rapidly developed even in the remoter mountain districts. But it was at Nuremberg that electrical science had found its most profitable application. The Schuckert factory employed 3,500 hands. It had grown from modest beginnings to its present proportions within 20 years. It undertook to provide installations for railways, tramways, and lighting in all parts of the world, but was only one of the great electrical enterprises that in modern days had been developed in Germany. Schuckert's factory was administered by a large staff of highly-cultivated superintendents, everyone of whom had gone through a course of training in one of the German technical institutes. Mr. Woodall's contention was that it was to the intellectual and technical capacity of the employer class and the chief superintendents engaged in the administrative direction of the new factories in Germany that their economic and commercial success was most attributable. After the usual advocacy of everybody knowing two or three or more foreign languages (even an electrical engineer cannot know everything), Mr. Woodall concluded with the somewhat dismal prophecy that in the application of electrical science in all parts of the world to multifarious uses we in England shall have to put forward energies of which there are no present sign if we are to maintain a position side by side with, not to speak of precedence over, our American and Continental competitors.

Inventions.—Writing in *Electrical Engineering* (Chicago), Mr. Fred De Land makes the following most mysterious and oracular remark: "The successful demonstration of the utility and commercial value of an ingenious protective device, the general introduction of which will probably render obsolete the product heretofore turned out by a great industry, and completely revolutionise existing methods of construction, affords a golden opportunity to further destroy confidence in electrical investments, and incidentally to line the pockets of the legal fraternity." We do not in the least know what particular protective device this refers to, but Mr. De Land then continues to make certain observations on inventions and patents in general, and American patent law in particular. "The moment," he says, "the solution of the problem is made plain those who did not see it seek to belittle the achievement of the one man who did see it by the assertion that it was so exceedingly obvious and simple as to exclude the possibility of a demand upon the inventive faculties. This will not do. An invention does not cease to be meritorious because it is simple. Many of the greatest inventions are most simple. The test should be, not whether the mechanism is simple or complex, but whether the patentee has given the world something new; whether the public is richer for his contribution to the art; whether he has produced novel and beneficial results." And this recalls Mr. Lockwood's apt and witty answer in a certain infringement suit: "Little further comment is required, but it may be added that the same line of reasoning which was adopted by Mr. Expert in discussing that patent is available to prove that the electromagnet as it left the hands of its great inventor, Prof. Henry, is a complete anticipation of the dynamo-electric machine, invented many years thereafter; and adopting such reasoning, we may say that by extending the core of the said electromagnet at both ends, turning the same into journals, providing bearings wherein the said journals shall revolve, and by placing the magnet so altered between the poles of a horseshoe permanent magnet or electromagnet, and then by mounting a pulley or a crank on one end of the core of the first magnet, and by connecting its coils in the desired way, with the coils of the electromagnet between whose poles the first magnet is placed, we thus have a complete anticipation of the invention of the dynamo. And it is not difficult to prove in the same logical manner that a boa constrictor is exactly the same thing as an elephant; for it may with a good show of reason be said that by simply cutting off 12ft. of the serpent's tail and sewing it on to his head, and by providing him with four legs and a new tail, and by giving him a pair of tusks and fitting him internally to eat grass and hay, we thus have a complete anticipation of the elephant."

THE PRINCIPLES OF ALTERNATE-CURRENT WORKING.*

BY ALFRED HAY, B.Sc.(EDIN.), A.I.E.E.

(Continued from page 427.)

79. One of the most striking and important points of difference between continuous and alternating currents lies in the fact that whereas the former will only flow in a circuit which is wholly conducting, the latter will, on the other hand, flow in a circuit part of which is composed entirely of non-conducting material. The ability of an alternating current to traverse insulators gives rise to some interesting and somewhat complicated effects; many of these are usefully applied in practice. In considering effects of this nature, we have to deal with a class of phenomena which are entirely absent in the case of continuous currents.

80. The student who has been mainly concerned with the study of continuous-current phenomena will at this stage have to endeavour and enlarge the somewhat limited and one-sided views of matters electrical which such a study is apt to engender. He must learn to think of alternating currents as passing not only through conductors, but through such bodies as bits of glass or guttapercha, oils, air spaces, etc.—*i.e.*, through insulators or *dielectrics*—without destroying them or altering their nature; and to remember that in all such cases the current produces precisely the same *magnetic effect* as that which is characteristic of it when flowing in a conductor.

The mechanism by which a current is conveyed along a conductor—whatever the ultimate nature of that mechanism may be—is different from that by which it passes through a dielectric. In order to distinguish between the two modes of conduction, it is usual to refer to currents passing along conductors as *conduction currents*; the varying currents which are capable of traversing a dielectric being termed *displacement currents*. These terms are convenient, but the student must be warned against the notion that there are *two kinds* of current which differ from each other in their effects; a conduction current is in every way similar to, and produces the same effects as, a displacement current, and the two terms merely relate to the nature of the medium through which the (same) current passes.

Probably the best method of introducing the student to the study of displacement currents is to have recourse to a very rough but useful hydraulic analogy. This is accordingly the method which we shall follow in dealing with the subject.

81. In Fig. 59 let P A B represent a circular closed pipe, inside which is a piston P which fits it exactly, and which is capable of sliding freely inside the pipe. We shall suppose the pipe to be completely filled up with a viscous incompressible liquid. If the piston, P, be caused to move round the pipe, a flow of the liquid will take place in the pipe, and this flow will be due to the difference of pressure on the two sides of the piston. If we suppose the liquid to be initially at rest, and a steady force to be applied to the piston, then, owing to the inertia due to the mass of the liquid, the velocity will increase gradually until a steady flow is produced. While the flow is variable the force driving the piston does work in two ways: (1) by imparting kinetic energy to the moving mass of liquid; (2) by overcoming the resistance to motion which is due to the viscosity of the liquid. The first portion of the energy is stored up; the second is dissipated in producing heat. When the flow has become steady no further storage of energy takes place; the whole of the energy supplied is now being dissipated in the form of heat. The rate of flow (which is measured by the quantity of liquid that flows past any cross-section of the tube in unit of time) which results for a given driving force applied to the piston will depend on the resistance offered to the motion by the viscosity of the liquid; a less viscous liquid will attain a greater velocity than a more viscous one. Let us suppose that after the flow has been going on for some time the steady force propelling the piston is suddenly removed. Owing to the inertia of the liquid, the flow will not cease suddenly but will go on for a time, the liquid pushing the piston in front of it. The force propelling the piston is now derived, not from any external source, but from the kinetic energy stored up in the moving liquid. Since no further supply of energy takes place, it is evident that the motion will gradually subside, the kinetic energy of the liquid taking the form of heat.

82. For the pipe enclosing the liquid substitute a closed conducting circuit, for the piston a source of E.M.F., and we get a rough and very imperfect, but nevertheless useful, method of picturing to our minds the actions which are involved in starting, maintaining, and stopping a current in a circuit. The rate of flow of the liquid corresponds to the current, the viscosity of the liquid to the resistance of the circuit, the mass of the liquid to the inductance of the circuit. The energy stored up in the moving liquid corresponds to that stored up in the magnetic field produced by the current. In each case, while the flow lasts, we have the transformation of energy into heat.

83. As we shall pursue this analogy somewhat further, and apply it to the case of a circuit a portion of which consists of non-conducting material, it will be necessary once more to warn the student against the notion that the analogy is intended to represent the actual mechanism of conduction. Analogies are very useful if not abused and mistaken for the actual systems which they are intended to illustrate; but if pressed too far, they may become sources of danger, and give rise to utterly erroneous ideas. In order to show the student how imperfect our analogy is, and thus put him on his guard, we shall draw his attention to one important

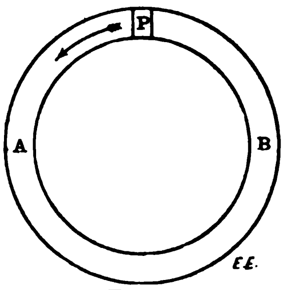

FIG 59.

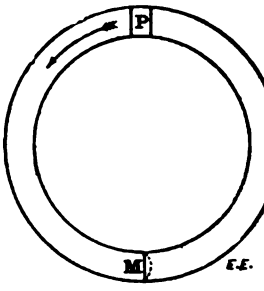

FIG. 60.

matter in which our hydraulic analogy signally fails. The kinetic energy of the moving liquid has its seat in the liquid itself, so that the energy is contained within the pipe. But in the case of an electric circuit, we know that in most instances the magnetic field spreads out into the surrounding space, and the bulk of the stored energy will have its seat not in the conductor itself, but in the space surrounding it (or, more correctly, in the *ether* which fills that space).*

84. Instead of the simple pipe shown in Fig. 59, let us next suppose that we have a similar pipe, but furnished with an elastic membrane, M (Fig. 60), which does not allow any flow of liquid to take place across it. Such a membrane would correspond to an insulator interposed between the two ends of a conducting circuit. If we suppose that the membrane is strong enough to resist any pressures which may be brought to bear upon it, then it is obvious that no continuous flow can take place in such a circuit. But since we have supposed the membrane to be elastic, it follows that if a force be applied to the piston, P, the pressure will be transmitted through the liquid in the direction of the arrow, and this pressure acting on the elastic membrane, M, will cause the latter to bulge (as shown by the dotted line), so that a *temporary* flow of the liquid will take place. Imagine the pressure to be gradually increased. The membrane will bulge more and more, and

* Based on a series of evening lectures delivered at the University College, Liverpool.

* Another important point on which the hydraulic analogy is misleading is the following. According to this analogy, the phenomenon of an electric current consists of actions which go on entirely inside the conductor; whereas according to modern views the most important actions which constitute an electric current take place *outside* the conducting circuit. The current is supposed to consist in the motion of tubes of electrostatic induction which, starting from the source of E.M.F., sweep across the space bounded by the circuit, the ends of the tubes gliding along the surface of the conductor, until the tubes enter the conductor, and thus become dissolved or destroyed.

Digitized by Google

the *state of strain* produced in it will increase, until when a certain pressure is reached the membrane gives way, being ruptured; when rupture of the membrane has taken place, a steady flow becomes possible.

Returning now to the electrical case, let us suppose that we have a source of E.M.F., P (Fig. 61), connected to an arrangement, M, of two conductors separated by a dielectric; such an arrangement is generally called a *condenser*. When the E.M.F. is first introduced into the circuit there is some sort of elastic yielding of the dielectric which corresponds to the elastic yielding of the membrane in the hydraulic analogy. This yielding of the dielectric constitutes a *displacement current*. During the yielding a certain *quantity* of electricity (so called) passes into the condenser; this corresponds to the quantity of liquid which fills the space rendered vacant by the bulging of the membrane, M (Fig. 60). If the E.M.F. is gradually increased the strain in the dielectric will increase in proportion, until ultimately the material breaks down, a spark passing through it; thus an *arc* is established between the two conductors, through which a continuous current now becomes possible.

85. The quantity of electricity which passes into a condenser when a P.D. is established between its terminals depends on the amount of elastic yield in the dielectric, and this latter quantity is in direct proportion to the applied P.D. Hence we may write

$$\text{quantity} = C \times \text{P.D.},$$

where C is a certain constant quantity independent of the P.D. This constant quantity is termed the *capacity* of

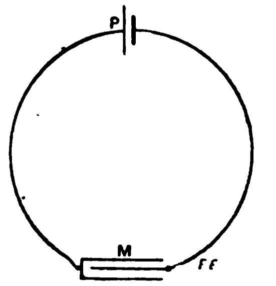

Fig. 61.

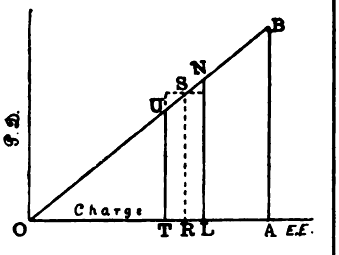

Fig. 62.

the condenser. If Q, C, and V stand for the quantity, capacity, and P.D. of a condenser respectively, then the relation connecting these quantities is

$$Q = C \times V.$$

Since, when $Q = 1$ and $V = 1$, C is also equal to 1, it follows that a condenser of unit capacity is one which is charged to unit P.D. by unit quantity.

The practical unit of capacity is the *farad*, and it is defined as the capacity of a condenser which is charged to a P.D. of one volt by a quantity of one coulomb. For practical purposes the farad is too large a unit, and it is usual to express capacities in terms of the *microfarad*, which is one-millionth of a farad.

It is not difficult to deduce an expression for the amount of energy stored up in a condenser. The relation between the quantity and P.D. is represented by a straight line, such as O B in Fig. 62. Let us suppose that the condenser is charged to a P.D. of V C.G.S. units by a quantity of Q units (C.G.S.). If O A in Fig. 62 is made equal to Q, and A B to V, then C, the capacity of the condenser, is equal to $\frac{Q}{V} = \frac{OA}{AB}$. Let us suppose that at a certain stage during the charging the quantity is O T, the corresponding P.D. being T U; and let us calculate the work done in increasing the charge by a small amount T L. While a quantity T L is being introduced into the condenser, the P.D. rises from T U to L N, and its mean value between these limits is R S (T R being equal to R L). Now it follows from the definition of potential that in transferring T L units of quantity against a P.D. of R S units an amount of work is done which is represented by T L × R S. But the latter product represents the area of the strip T U N L. Hence, the work in ergs done in increasing the charge by an amount T L is represented by the area of the strip T U N L. Applying this result to each successive increment of the charge, we see that the total amount of energy stored up in the condenser is represented by the area of the triangle O A B, and hence is equal to $\frac{1}{2}$ O A × A B—*i.e.*, to $\frac{1}{2}QV$. This result may also be written in either of the forms $\frac{1}{2}CV^2$ or $\frac{1}{2}\frac{Q^2}{C}$.

86. Returning to Fig. 60, let us suppose in the first place that the liquid used is an extremely viscous one, offering a considerable resistance to motion. On applying a force to the piston, P, the liquid is caused to flow slowly, distorting the membrane, M, until the latter takes up a certain permanent position, depending on the difference of pressure on its two sides. Translated into the electrical case, this means that when a condenser is charged through a very high resistance the charging current is unidirectional. Suppose, in the second place, that we have a liquid of very high density—*i.e.*, possessing considerable *mass* per unit volume—which is extremely mobile. If a constant force is suddenly applied to the piston, P, the liquid will be gradually set in motion, a (positive) flow taking place while the membrane is being distorted. But owing to the considerable inertia and absence of internal friction the liquid will *tend to move on* after the membrane has taken up its equilibrium position. Hence the membrane will overshoot its mark, and a series of to-and-fro oscillations will take place, the flow of the liquid taking place in alternate directions and with gradually diminishing amplitude, until the whole of the kinetic energy has become dissipated, and the membrane taken up its position of permanent distortion. The less the viscosity of the liquid the longer will be the time throughout which these oscillations persist. It is also evident that while the oscillations are going on the difference of pressure on the two sides of the membrane alternates between values which are successively above and below that reached when a permanent distortion of the membrane has set it. Translating once more into the electrical case we find that if a condenser is charged through a circuit of high inductance and very low resistance the charging current is not unidirectional, but *alternating*, with gradually diminishing amplitude; and the P.D. at the condenser terminals undergoes oscillations, rising above and falling below the E.M.F. of the charging battery.

87. Although the occurrence of certain actions in the hydraulic analogy is *no proof* that similar effects must occur in the electrical case, yet we may reason from the better known to the less known, and then leave it for direct experiment to decide whether the analogy has been pushed beyond legitimate limits or not. In the case under consideration experiment has shown that our deductions are correct for the electrical case; that under certain conditions oscillations such as we have been considering actually do take place.

When the time-current curve for an oscillatory charge is determined it is found to consist of positive and negative half-waves of gradually diminishing amplitude (but the same period), so that the area of each positive half-wave exceeds that of the succeeding negative half-wave, and therefore a certain quantity of electricity enters the condenser after each complete wave. The excess of the areas of the positive over those of the negative half-waves measures the charge (or quantity of electricity) in the condenser.

Since the P.D. at the condenser terminals during an oscillatory charge rises periodically to values in excess of the charging E.M.F., it follows that a condenser which is strong enough to stand a unidirectional charge from a given source of E.M.F. might break down with the same E.M.F. if the conditions of the circuit are such as to produce oscillations.

What has been said with regard to the *charging* of a condenser applies also to its *discharge*, and under certain conditions the discharge of a condenser becomes oscillatory.

From the explanations given above it follows that although, so long as the elastic membrane remains intact, no *steady flow* can take place in a system such as that shown in Fig. 60, yet if the pressure on the two sides of the piston in Fig. 60, and the E.M.F. in Fig. 61, be made to alternate, the elastic membrane in the one case and the condenser in

Digitized by Google

the other *will respond* to the *alternating* pressure, and we thus see that an alternating (displacement) current is capable of passing through a dielectric.

88. In our hydraulic analogy, the rate of flow at any instant is measured by the quantity of liquid passing per second through any cross-section of the circuit. In the electrical case, the current at any instant is measured by the rate at which "quantity of electricity" is being transferred through any cross-section of the circuit. But the quantity which is so transferred passes into the condenser. Hence *the current is measured by the rate of change* (*Art 5*) *of the quantity in the condenser.* This result we shall frequently have to make use of in what follows.

RAILWAY BLOCK SIGNALLING.

BY J. PIGG.

(Continued from page 429.)

Fig. 76 represents a portion of the main line of one of the through routes to the North. Two important lines

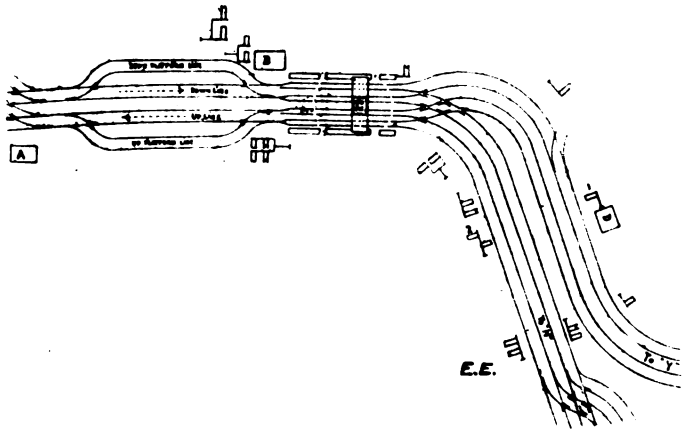

FIG. 76.

from the north and east converge upon a swingbridge crossing a navigable river. All four sets of rails are carried over the swingbridge, but the two "up lines" and the two "down lines" are "bunched," and the bridge is little wider than would be required for the ordinary double line of rails. At the south end of the bridge the lines widen again owing to the station platform lines being distinct from the running lines. Consideration of Fig. 76 will show the necessity for extra precautions in working this section of line, owing to the possibility of accident resulting from the fouling of the lines at the north end of the bridge, and from the presence of the bridge itself.

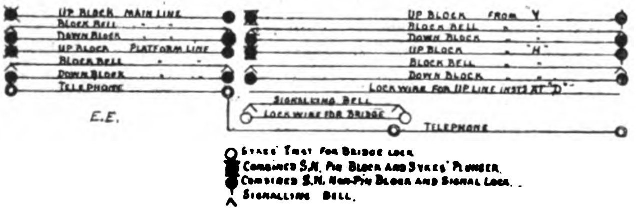

FIG. 77.

This portion of line is divided into two block sections, A B and B D (Fig. 76); C is a cabin on the swing portion of the bridge in which is installed the control of the hydraulic machinery for operating the bridge for the passage of river traffic, but although it is provided with electrical apparatus, connected with B, by which the operation of the bridge is controlled, it is entirely dissociated from the block working of the section B D, in which it is situated. The signalman at B is in this case the person controlling the operation of all traffic on to the bridge from either direction; and he also controls indirectly the river traffic by means of the apparatus by which the bridge is locked in the position for the passage of railway traffic.

The line is worked by three-wire single-needle block instruments, to which is added an adaptation of Sykes's lock and block to the indicators for the two up lines between D and B. The operation of the bridge is controlled by Sykes's instruments also, and the handles of the two down-line instruments are connected with the signal locking at B.

Fig. 77 is a diagram showing the wires used for signalling and locking between A and B, B and D, and B and C. The construction of the up-line block instruments at B, working to D, is shown by Fig. 78, and the additional apparatus to the corresponding instruments at D is shown by Fig. 79. So far as the block instruments themselves are concerned, they differ in no way from others previously shown, and the novelty of the arrangement consists in the addition of the lock bars, M *n* O, the continuation of the lever, L, and the plunger, P (Figs. 69, 70, 71), for specific purposes. Practically, the apparatus shown by Fig. 68 is split into its two component parts, the plunger and its locking apparatus being added to the "up" line instruments at B, and the signal locking, or receiving portion of the complete instrument, consisting of the polarised electro-magnet, armature, etc., being added to the corresponding

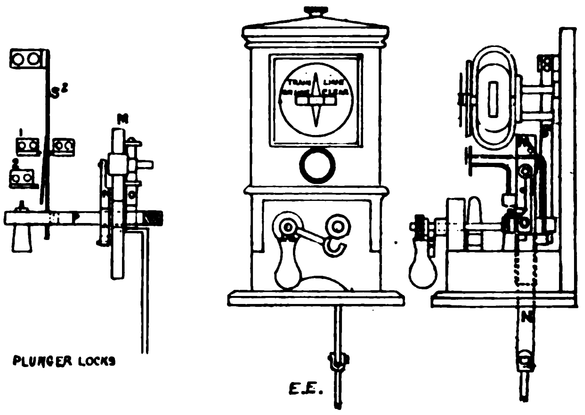

FIG 78.—S.N. Instrument with Sykes' Plungers.

instrument at D. The special bridge locking apparatus is shown by Fig. 80, the arrangement of apparatus at C being identical with those at B. The apparatus is practically the same as is shown by Fig. 68, with the exception that S^1 and the other connections for the semaphore indicator are omitted as the latter is not

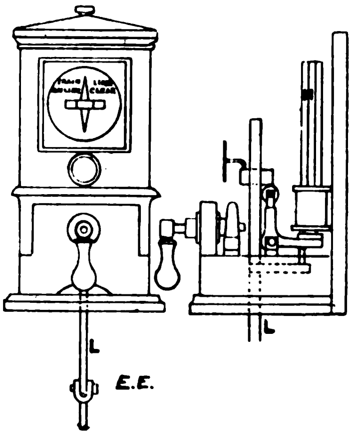

FIG. 79.—S.N. Instrument with Sykes' Signal-Locking Apparatus.

used. The handle of the switch, T (Figs. 69 and 71), is retained, but it is merely mechanical in the present arrangement. The general arrangement of the instruments at B relatively to the signal levers working the signals, points, clearance bars, and inter-cabin control is shown by Fig. 81, together with the interlocking of the "down" line instruments to A with the lever locking. Fig. 82 shows the electrical connections for the locking apparatus between B and C and B and D. The connections of the block instruments are not given, for reasons already adduced. It will be observed that the locking and indicating apparatus of

Digitized by Google

the additions to the up-line block instruments at B and D are operated by one lever instead of by two, as in the ordinary arrangement of Sykes's instruments for block working, and this of course follows from the separation of the different parts. The levers, N, operating the plunger locks at B are connected together, as shown diagrammatically in Fig. 81, so that only one plunger can be used at once. The plunger of either instrument can only be depressed *after* the lever operating the rod, N, of that instrument has been moved into position for a train to approach on that line, and as this

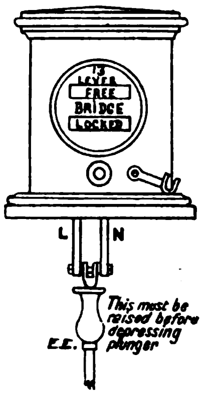

FIG. 80.—Bridge-Locking Apparatus.

lever is interlocked mechanically with other levers necessary to that particular line, it follows that the road must be completely set at B before either of the electrical locks at D can be released, and even then only the lock controlling the signal for one particular line can be released.

The signals 1 2 (Fig. 76) at D are those which are under electrical control from B. The levers, at D, working these signals are also connected, so that the operation of the lever for one of them locks the rod, L, of the other instrument, so that it cannot be released by a current from however sent. This is an additional check from against fouling at the north end of the bridge, and is quite independent of

B controls the down-line signals at A by lever 15 (Fig. 81), and this lever is interlocked with the handle, M_1, which, when placed vertical, causes the down-line instruments at A and B to indicate "Train on line." Hence, so long as the mechanical signals are obeyed, the bridge is protected against the approach of trains from A on the "down" line.

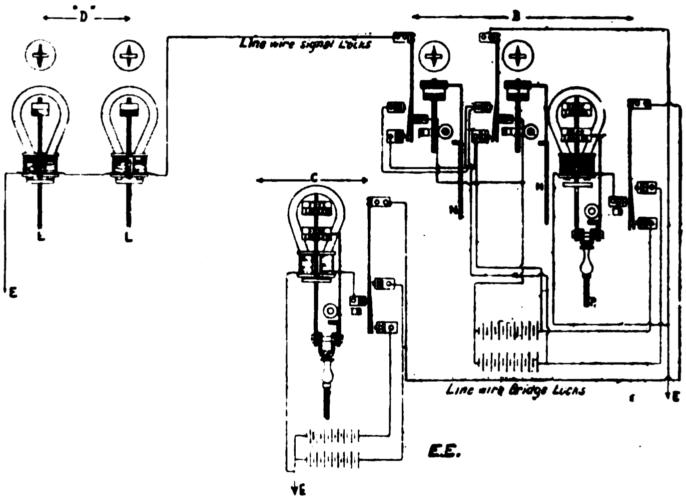

FIG. 82.

When it is necessary for the bridge to be opened for river traffic, C notifies B by the code arranged for use with the separate bell circuit. When the latter is ready, after performing the operations indicated for the protection of the down line, etc., he operates the bridge lock lever (13, Fig. 81) and raises the lever, P_1, by hand, and by depressing the plunger unlocks the instrument at C, enabling him to make the preliminary arrangements for opening the bridge. C then raises the rod, P_1, of his own instrument, and by depressing the plunger locks the lever 13 at B in the open position, and thus prevents it being inadvertently put back. Under these conditions C is master of the situation, and

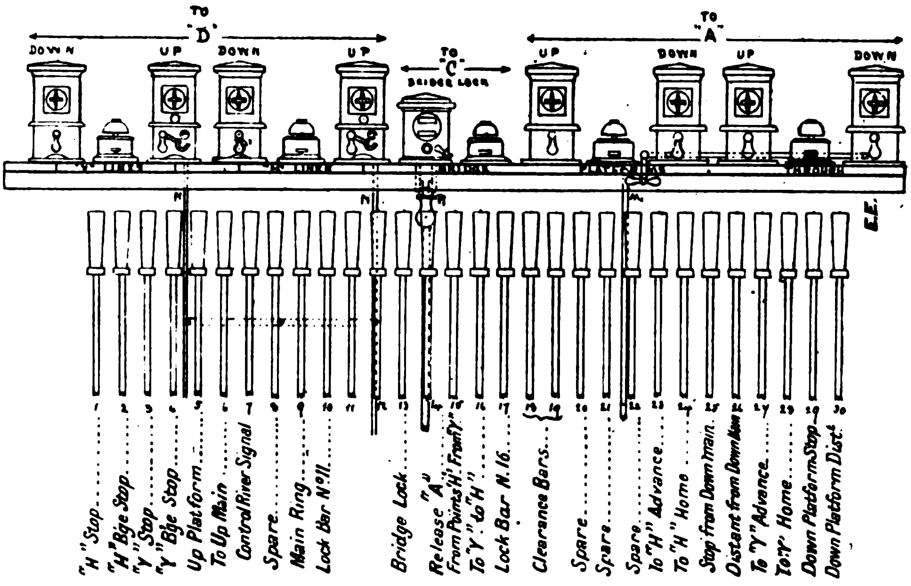

FIG. 81.

the action of the plunger locks and the connection existing between the two rods, N and B.

As will be seen, B effectually controls the approach of trains from D, and so long as the apparatus is in order and the mechanical signals are obeyed it is impossible for trains to foul each other at the north end of the bridge. Fouling between a train passing from B on the "H" line and a train approaching B on the "Y" line is provided against by the mechanical interlocking of the signal and point levers.

In addition to the provisions described for ordinary working over the "bunched" part of the block section, B D, provision has to be made for blocking all four lines from both directions during the time the bridge is open for river traffic. The up lines from D to B have been described.

B is unable to undertake any operation involving the approach of trains from either A or D. When the bridge is again ready for railway traffic the operations are reversed, and C becomes dependent again upon B for permission to operate the bridge on the succeeding occasion.

(To be continued.)

A Bright Magazine.—We are in receipt of a copy of the *English Illustrated Magazine* for November. In this number, as in previous ones, a marvellous amount of interesting reading matter is given for the humble sixpence, and it is, moreover, sufficiently varied in character to please all readers. The numerous illustrations are also very well executed.

COMPARISON AND REDUCTION OF MAGNETIC OBSERVATIONS.

Report of the Committee, consisting of Prof. W. G. Adams (*Chairman*), Dr. C. Chree (*Secretary*), Lord Kelvin, Prof. G. H. Darwin, Prof. G. Chrystal, Prof. A. Schuster, Captain E. W. Creak, The Astronomer Royal, Mr. William Ellis, *and* Prof. A. W. Rucker, *to the British Association.* (*Drawn up by the Secretary.*)

Introductory Remarks: "*Non-cyclic*" *Effect.*

§ 1. An analysis of the results from the Kew declination and horizontal force magnetographs during the selected "quiet" days of the five years 1890 to 1894 was submitted last year to the committee and adopted as its report for 1895. The corresponding inclination and vertical force results had also been pretty fully worked up, but I held them over pending an enquiry into the sufficiency of the temperature correction. Some considerable time may elapse before these results can be utilised to full advantage. It has thus seemed inexpedient to defer dealing with one set of phenomena whose general character is unaffected by any uncertainty as to the temperature correction, and whose existence seems to render desirable a reconsideration of the whole system of "quiet" day observations. The phenomena in question bear on what I termed last year the *non-cyclic* effect.

Supposing H_0 and H_{24} to denote mean values of the horizontal force at the first and second midnights of a selected series of days, then $H_{24} - H_0$ was defined as the non-cyclic effect or variation of horizontal force; and a similar definition applies in the case of any other element.

Non-cyclic Effects During Six Years, 1890-1895.

§ 2. It is proposed to give here complete data as to the non-cyclic effects in the selected "quiet" days at Kew during the last six years. To some extent this incorporates results given last year, but it seemed desirable to show side by side the results for all the elements throughout the same series of years.

There are five selected "quiet" days a month, and so a total of 360 in the 72 months of the six years considered. In November and December, 1890, however, the vertical force magnetograph was out of action, which reduces by 10 the number of days available in the case of the vertical force and inclination.

Table II. gives the mean results for the several quarters of the year as deduced from Table I., while Table III. gives the annual means for the individual years.

Table III.—*Mean Non-cyclic Effect per "Quiet" Day for Each Year.*

Year.	Declination.	(Horizontal force) × 10^6.	(Vertical force) × 10^6.	Inclination.
1890	− 0′·36	+23	+15*a*	− 0′·10*a*
1891	+ ·29	+23	−12	− ·18
1892	+ ·14	+53	−20	− ·41
1893	+ ·26	+40	−26	− ·35
1894	+ ·15	+33	+12	− ·18
1895	− ·05	+44	−15	− ·33

a. In 1890 the means of vertical force and inclination are based on the results of only 10 months, in one of which (March) an abnormally large positive non-cyclic effect was recorded in vertical force.

Relation of Non-cyclic Effects to Annual Changes.

§ 3. To see the full significance of these data, regard must be had to the magnitudes of the annual changes of the several elements. Table IV. gives these for the period considered, along with the number of average "quiet" days, which, according to Table I., would have sufficed to produce changes numerically equal to the annual changes observed.

Table IV.

—	Declination.	Horizontal force	Vertical force.	Inclination.
Mean annual change, 1890-95	− 6′·8	21×10^{-5}	-19×10^{-5}	− 1′ 9
Number of "quiet" days producing equal change	95 *b*	6	23	7½

b. In the case of declination, and it alone, the non-cyclic effect is opposite in sign to the secular variation.

The figures relating to the horizontal force and inclination are so significant that comment in their case seems unnecessary.

As regards the declination and vertical force in individual months, notably January, the non-cyclic effects have been as large and consistent as with the other two elements, but in general this has been far from the case. As Table III. shows,

TABLE I.—Non-cyclic Effect from Six Years, 1890-1895 (Mean per "Quiet" Day).

Month.	Declination. Effect.	Declination. Individual months. +	0	−	Horizontal force (Effect) × 10^6	Horizontal force Individual months. +	0	−	Vertical force. (Effect) × 10^6	Vertical force Individual months. +	0	−	Inclination Effect.	Inclination Individual months. +	0	−
January	+0′·63	6			+50	5		1	−52			6	−0′·47	1		5
February	+ ·33	4		2	+57	5	1		+ 5	3		3	− ·35	1		5
March......	+ ·18	3		3	+28	5	1		+13	2	2	2	− ·17	1	1	4
April	+ ·12	3	1	2	+20	4	1	1	−22	2		4	− ·20	1	1	4
May	+ ·07	3		3	+38	5	1		−12	3		3	− ·27	2		4
June	− ·17	3		3	+22	4	1	1	−28	1		5	− ·22	1	1	4
July	− ·23	3		3	+27	4	2		−13	1		5	− ·22		2	4
August	− ·30	1	1	4	+37	5		1	− 8	3		3	− ·27		1	5
September......	+ ·12	3		3	+38	6			+30	3	1	2	− ·18	1		5
October	+ ·03	2	1	3	+50	6			+ 5	3		3	− ·28	1		5
November	+ ·18	3	1	2	+53	6			−12	2		3	− ·40			5
December	− ·10	1	2	3	+15	5		1	− 6	2		3	− ·12		2	3
Annual mean	+0′·072	—			+36·4	—			−8·3	—			−0′·263	—		
Totals of months......	—	35	6	31	—	60	7	5	—	25	3	42	—	9	8	53

In the case of the declination + signifies a deflection to the west. The true secular variation at present is towards the east. The components of force are measured in C.G.S. units.

TABLE II.—Mean Non-cyclic Effect per "Quiet" Day for Each Quarter of the Year.

Quarters	Declination. 1	2	3	4	(Horizontal force) × 10^6. 1	2	3	4	(Vertical force) × 10^6. 1	2	3	4	Inclination. 1	2	3	4
Effect	+0′·38	+ 01	−·14	+ ·04	+45	+27	+34	+39	−11	−21	+3	−4	−0′ 33	− ·23	− 22	− ·28

In Table I. the six Januarys, six Februarys, etc., of the six years have been combined together so as to show the values of the cyclic effects at different seasons of the year. The figures under the heading "Individual months" show in how many of the six Januarys, etc., the effect was an increase of the element in question was nil, or a decrease. At the foot of the table appear the mean non-cyclic effects per "quiet" day throughout the six years and the totals of the several columns under the headings "Individual months."

in two years out of the six both declination and vertical force have exhibited a mean non-cyclic effect opposite in sign to that supplied by the six years as a whole.

In considering such a phenomenon one ought of course to remember that it is contrary to probability that any 60 arbitrarily selected days—the number on which an annual mean is based—will produce a diurnal variation truly cyclic after allowance is made for the normal annual change; and thus part of the irregularity exhibited by Table III. may

A. In declination. B. In horizontal force. C. In vertical force. Mean yearly excess of "quiet" day value in declination = +0′·05; in horizontal force = +34; in vertical force = −8.

reasonably be attributed to pure chance. When, however, one looks at the uniformity of sign in the non-cyclic effects in the horizontal force and inclination exhibited in Table I., and remembers that the monthly means in that table are based on only 30 days, one must, I think, conclude that the variability of sign in the declination* and vertical force† results, at least in Table III., has probably a true physical basis.

Mean Annual Values from "Quiet" and Unrestricted Days.

§ 4. Table IV. is merely a plain statement of facts; but if too exclusively considered it might unquestionably convey an exaggerated idea of the defects attaching to the ordinary use made of "quiet" days at the present time. At Kew Observatory they are employed to get out the mean diurnal inequality for summer and winter and the whole year, as well as the mean annual values of the several elements.

As regards the mean annual value of an element, the quantity "mean value from 'quiet' days less mean value from all days" may be irregularly positive and negative, or like the non-cyclic effect in the element it may be normally of one sign. It would certainly be desirable to know which of the alternatives is true. The meaning to be attached to the secular variation deduced from two consecutive years or from a short series of years would be much more uncertain if the former alternative represented the facts than if the latter did.

In the Greenwich "Magnetical and Meteorological Observations" tables are published showing the diurnal variations both in "quiet" and unrestricted days, but not apparently direct information as to the difference between the absolute values of means deduced from the "quiet" and from unrestricted days.

At St. Petersburg, and then at Pawlowsk, it has, however, long been customary for Dr. Wild to select a series of normal "quiet" days whose results are dealt with alongside of those from unrestricted days. The principle of selection guiding the choice at Pawlowsk and Greenwich has probably been slightly different, but there is at least a strong presumption that the differences between the annual means from unrestricted days and from the the Astronomer Royal's "quiet" days will prove to be of the same character as the corresponding differences observed in the case of Wild's "quiet" days.

§ 5. The annual means for all the elements at St. Petersburg, from both "quiet" and unrestricted days, for some 12 to 16 years preceding 1885 are given in a paper by Dr. Müller in the "Reportorium für Meteorologie," Bd. XII., No. 8. In the case of every element, according to Müller's tables 20 to 23, the sign of the quantity "'quiet' day mean less unrestricted day mean," was uniformly, or practically uniformly, of one sign; and the secular variations deduced from the "quiet" and unrestricted day results, even for consecutive years, showed a remarkably good agreement. The following summary of the mean results deducible from Müller's tables is extracted from a recent paper by Leyst ("Rep. für Met.," Bd. XVII., St. Petersburg, 1894, No. 1, p. 109).

* In 1890 a *positive* non-cyclic effect appeared in only one month (January); in 1891 a *negative* effect in only one month (November).

† In both 1890 and 1894, however, a slight majority of individual months exhibited a *negative* non-cyclic effect as usual.

‡ The number in most of the earlier years dealt with by Dr Müller seems, however, to have been considerably greater.

Wild's Normal Days—all Days (Annual Means).

Declination west	+0′·25.
Inclination	−0′·23.
Vertical component	$-10^{-6} \times 8$ C.G.S. units.
Horizontal component	$+10^{-6} \times 35$,,

Tables of the monthly and yearly means for Wild's "quiet" days and for unrestricted days at Pawlowsk continue to be given in the "Ann. des Phys. Central-Observatoriums." The results from the last two volumes are as follows:

Wild's Normal Days—all Days (Annual Means).

Year.	Declination.	Horizontal force.	Vertical force.
1893	+0′·3	$+10^{-6} \times 40$	$-10^{-6} \times 30$
1894	+0′·6	$+10^{-6} \times 60$	$-10^{-6} \times 10$

There would thus appear to be no essential change in the phenomena since the period to which Müller's paper refers.

§ 6. Wild's "quiet" days numbered only 25 in 1893 and 33‡ in 1894, as against the Astronomer Royal's 60 a year; thus the results from the latter are likely to exhibit even less irregularity in their departures from the results of unrestricted days than the former. Mere surmises, such as the preceding, are vastly inferior to the actual numerical facts. Before deciding on the labour necessary to obtain the facts, one has first, however, to estimate their probable value. One factor in this consideration which the practical man can fairly urge is that accuracy in *absolute* value to anything like 1×10^{-5} in the case even of the horizontal force is an ideal we can hardly claim to have reached in this country.

Relation of Non-cyclic Effects to Diurnal Ranges.

§ 7. An idea of the amount of uncertainty which the non-cyclic effect may introduce into the mean diurnal inequalities for summer, winter, and the whole year may be derived from Table V. It gives the ranges of the elements, uncorrected for non-cyclic effect, as published annually in the Kew "Report," along with particulars as to the ratios borne by the mean non-cyclic effects to the corresponding ranges. In the case of the vertical force and inclination the year 1890 has been omitted as the results for it are not altogether complete.

§ 8. Table V. shows how much more important relatively the non-cyclic effect is in the winter than in the summer half-year.

In the winter half-year we see that the non-cyclic effect in both horizontal force and inclination is equal to about one-fifth of the range. This does not of course imply that there is an uncertainty of 20 per cent. in the range, because, whatever be the nature of the correction applied to eliminate the non-cyclic effect, it is hardly likely to introduce more than a small fraction of the observed difference between 0 and 24 hours into the algebraic difference of the maximum and minimum readings. The interval of time between these readings is in most cases nearer 6 hours than 12. The fact, however, remains that in some individual winters the uncertainty as to the range must be very appreciable. When we come to individual winter months, notably January, when the observed range is least, the uncertainty is apt to be considerable.

The preceding remarks refer exclusively to the uncertainties which the existence of the non-cyclic effect introduces into

Digitized by Google

diurnal ranges deduced from "quiet" days. Previous reports of the committee* have dealt with differences between the ranges deduced from unrestricted and from "quiet" days. It seems to me, however, that such comparisons are open to criticism so long as the proper treatment of the non-cyclic effect remains uncertain.

Relation of Non-cyclic Effects to Diurnal Inequalities.

§ 9. In the yearly and half-yearly results the most critical point is the nature of the diurnal inequality in the late night and early morning hours. The observed variation is then small, especially in winter, so that a disturbing element of no great absolute magnitude might completely alter the character of the phenomena. This will appear at once on reference to the curves of declination and horizontal force in last year's report, pp. 212 and 220. The curves on p. 220 are certainly suggestive of the presence of some abnormal influence during the midnight hours; at the same time this is not more true of them than of curves of the same type for Greenwich which Sir G. B. Airy† based on data derived from all days but those of considerable disturbance.

Elimination of Non-cyclic Effect.

§ 10. If diurnal inequalities are to be got out at all from "quiet days" in a form suitable for harmonic analysis, they must be made cyclic, and there is certainly no simpler way of doing this than that adopted last year—viz., treating the observed data as if the non-cyclic effect proceeded uniformly throughout the 24 hours. This method of treatment does not prejudice the facts. Supposing the non-cyclic effect to proceed irregularly throughout the 24 hours, then it may most conveniently be analysed into terms, one being a linear function of the time, the others periodic functions whose periods are 24 hours or sub-multiples thereof. The linear term is eliminated by the method adopted last year. The cyclic terms of course remain, and are incorporated with the other cyclic terms of like period which go to make up the diurnal inequality on "quiet" days. It would, however, be impossible to separate the two sets of cyclic terms by any mathematical device without an addition of physical facts or a supply of theories in their place. One way of obtaining additional facts would be to compare for a series of years the constant coefficients in the harmonic analysis of the diurnal inequalities from "quiet" and unrestricted days. The accidental features introduced by the arbitrary nature of the choice of "quiet" days might, however, prove troublesome.

The term in the non-cyclic effect treated as a linear function of the time may in its turn be composed of a series of terms, some possibly fluctuating regularly with the season of the year, others possibly of very long period; its magnitude, at least in individual months, may depend in large measure on the accidental preference of one set of "quiet" days to another.

Associated Phenomena.

§ 11. It was pointed out last year (*l.c.* p. 213) that the elimination of the non-cyclic effect through a correction consisting of a linear function of the time was determined solely by considerations of convenience and mathematical simplicity. It was carefully explained (*l.c.* §§ 5, 6) that General Sabine and Dr. Lloyd had observed phenomena in magnetic storms so exactly the converse of those presented by the non-cyclic effect on "quiet" days as to suggest that the two classes of phenomena were interdependent; and the conclusion was drawn that if this interdependence were true the non-cyclic effect might be expected in reality to progress irregularly throughout the 24 hours.

These conclusions may now, perhaps, be regarded as more than surmises. In the *Met. Zeitschrift* for September, 1895, Dr. van Bemmelen has described phenomena he terms *Nachstörung*, which appear to be of the same general character as, if not identical with, what has been termed here the non-cyclic effect.

As the title he selected implies, Dr. van Bemmelen associates the phenomena very intimately with magnetic storms. His investigations have included data from a variety of stations; and whilst his theoretical conclusions may, perhaps, undergo modification in the future, his work certainly indicates that an increase of knowledge as to this outstanding phenomenon on "quiet" days is likely to be of service in the general theory of terrestrial magnetism.

§ 12. In the meantime it might be safest not to assume that the non-cyclic element is an effect, and a preceding magnetic storm a cause. The fact that the horizontal force, for instance, tends to rise abnormally fast during a "quiet" day may, of course, merely represent a recovery from an abnormal loss occasioned by a magnetic storm; but it is at least conceivable that the abnormal fall during a magnetic storm may be partly a consequence of abnormal increase preceding it, or the two phenomena may be effects of a common cause.

If "quiet" days, with no appreciable disturbance, were the rule, one might possibly determine with ease the relationships of any given "quiet" day to a preceding or succeeding disturbed day; but appreciable movements will usually be found both before and after a "quiet" day at no great interval of time. If the causes operating in large and small disturbances are the same, then it is not improbable *à priori* that a small disturbance within a day or two of a "quiet" day may have more to do with it than a large disturbance a week before or after. It should also be remembered that General Sabine found that whilst, as a rule, large disturbances lowered the horizontal and raised the vertical force, the opposite results ensued in a very considerable number of instances.

In proposing any additions to the existing "quiet" day system, or any substitute, it must be remembered that one of the main objects aimed at by its introduction was a substantial saving in the labour required to obtain comparable results from different observatories. The tabulation of the whole mass of curves was felt in most cases too serious a burden. Considerable light might be thrown on the question of the uniformity or variableness of the non-cyclic element throughout the day by a very simple addition—viz., curve measurements at the noons preceding and succeeding each "quiet" day. In the course of this paper other suggestions have been made, but they could be put into effect only at observatories prepared to tabulate all the curves.

In conclusion, I wish to acknowledge the assistance I have derived from discussing a variety of the points involved with Mr. T. W. Baker, chief assistant at the Kew Observatory.

APPENDIX.

Remarks by W. ELLIS, ESQ., F.R.S.

Having had the opportunity of reading Dr. Chree's report on non-cyclic magnetic effects, I would beg to be allowed to offer the following remarks:

I had read with great interest Dr. Chree's "Comparison and Reduction of Magnetic Observations," forming the report of the Magnetic Committee for the year 1895, in which he discusses the Kew magnetic results on "quiet" days for the years 1890 to 1894. I had lately commenced to work up in a similar way the corresponding Greenwich results in order to make comparisons between Greenwich and Kew, when treated for the same years in a similar manner. Interesting questions are involved, since it cannot be said to be at present known how far the magnetic changes at two places not remotely distant one from the other should be expected to be similar, and if not similar, to what extent there may be difference, and also whether any part of such difference might be instrumental. It is not satisfactory to compare results for one period with results for another place for a different period, because at any one place the phenomena may vary considerably at different times. But my work is not sufficiently advanced to enable me to put the results at present into shape; still I may perhaps give some information bearing on points now discussed by Dr. Chree. In Table I. he gives the mean non-cyclic effect for "quiet" days for different magnetic elements for each month of the year, deduced from the Kew observations of the six years 1890 to 1895. My numbers for Greenwich are for the five years 1890 to 1894. At Kew the non-cyclic change in declination is positive in the first five, and in the ninth, tenth, and eleventh months of the year, and negative in the remaining months. At Greenwich it is positive in the first five months and in the eleventh month, and negative in the other months. At both places the largest positive value is in January, Kew = +0′·63, Greenwich = +0′·46; the largest negative value is in August, Kew = −0′·30, Greenwich = −0′·42. Mean for year at Kew = +0′·072, at Greenwich = +0′·007. In horizontal force the non-cyclic effect at Kew is positive in all months, and similarly at Greenwich. The greatest values at Kew are (effect × 10^6 in C.G.S. units), in January, February, October, and November, +50, +57, +50, and +53 respectively; and similarly at Greenwich, the values being +62, +53, +73, and +57 respectively. Mean for year at Kew = +36, at Greenwich = +40. In vertical force there is considerable difference, both in magnitude and sign, between the non-cyclic effect in different months at the two places. The mean for year at Kew = −8, and at Greenwich = −18. In this comparison it is to be remembered that the Kew results depend on the observations of six years, and the Greenwich results only on those of five years.

As regards now the mean values in separate years (Table III.). Of the five years, 1890 to 1894, the non-cyclic change in declination is in the same direction in four of the five years at both places; in horizontal force in the same direction in all years, and in vertical force in three years. The actual numbers are:

Non-cyclic change.		1890	1891.	1892.	1893.	1894.
At Kew	in declination	−0′·36	+0′·29	+0′·14	+0′·26	+0′·15
At Greenwich	in declination	−0′·23	+0′·08	−0′·20	+0′·15	+0′·24
At Kew	in horizontal force	+23	+23	+53	+40	+33
At Greenwich	in horizontal force	+18	+37	+68	+44	+33
At Kew	in vertical force	+15	−12	−20	−26	+12
At Greenwich	in vertical force	−12	−8	−39	−24	−4

* "B. A. Report," 1886, p. 71. See also paper by Messrs. Robson and Smith, *Phil. Mag.*, August, 1890, p. 143.

† *Phil. Trans.* for 1863 and for 1885.

Digitized by Google

In vertical force there is a tendency to a uniformly greater negative value at Greenwich than at Kew. Considering, however, the values at each station separately, the greatest negative values occur in the same two years, 1892 and 1893, at both places.

One question that I had set myself to discuss was how far the absolute magnetic values—as, for instance, the mean monthly values differ as determined from the five "quiet" days in each month and as determined from all days (excepting those of excessive magnetic disturbance). In the Greenwich "Observations" there are given in Tables I., III., and VII. of the magnetic section mean daily values of declination, horizontal force, and vertical force respectively throughout the year (excepting days of excessive disturbance). The means of these values for different months are given in Table XI. Extracting from the different tables the values for the adopted "quiet" days, and taking the mean in each month, the variation of these means from the corresponding means of Table XI. gives in each case the deviation of the "quiet" days mean from that for all days. Since the mean of the five selected days falls always near the middle of the month, the comparison, for a first enquiry, sufficiently eliminates the secular variation, considering it uniform, the only possible supposition. The excess of the "quiet" day monthly mean above the all day or unrestricted monthly mean is in each month of the year for each element, as shown in Table A (average of five years 1890 to 1894).

The corresponding separate yearly differences are :

Greenwich.		1890.	1891.	1892.	1893	1894.
Excess of absolute	A	+ 0'·01	− 0'·12	+ 0'·07	+ 0'·19	+ 0'·12
"quiet" day value	B	+ 11	+ 37	+ 31	+ 37	+ 53
above all days value...	C	− 8	− 7	− 26	− 14	+ 14

A. In declination. B. In horizontal force. C. In vertical force.

I have not sufficient opportunity at the present moment to add much by way of discussion of these numbers, but taking the element in which the difference of absolute value is most marked—that of horizontal force—some few remarks may be offered. We see that the uniformly positive non-cyclic change on "quiet" days is accompanied by an increased absolute value of horizontal force on such days, as compared with the value from all days, as we should, perhaps, expect. At Greenwich, magnetic disturbance commonly causes diminution of horizontal force, after which the value works back to a more normal one. But there are years in which the magnetic registers are unusually quiet, with few disturbances of even moderate amount, as in the years 1878 and 1879. The inference would be that in such years the difference between the absolute value for the especially "quiet" days and that for all days should be small, varying to a certain extent in different years with the more or less prevalence of magnetic disturbance. I cannot, however, for the moment refer to the Pawlowsk differences of which Dr. Chree speaks, to ascertain whether they exhibit variations of this character. Further, whether the rise of value on "quiet" days represents a recovery from abnormal loss during disturbance, or whether the abnormal fall during disturbance is in any way a consequence of preceding abnormal rise, may be a question. But the view that the recovery on "quiet" days is rather a consequence of abnormal fall during disturbance—that is, that the disturbance is really the primary dominating factor, appears to receive support from the following consideration. When disturbance suddenly arise it seems to break out over the whole earth at precisely the same moment of absolute time (see *Proceedings*, Royal Society, vol. lii., p. 191). But an instantaneous magnetic shock sensible over the whole globe could scarcely, one would imagine, arise from action from within alone ; and since magnetic disturbances are more frequent when sunspots are numerically high, there seems reason to suppose that the exciting cause is in such cases mainly external. To pursue this matter is, however, rather to enter the region of speculation.

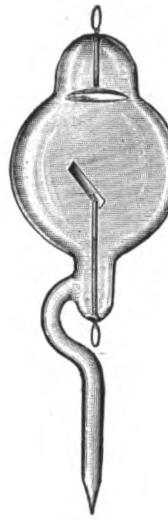
It may, perhaps, be remarked that the mean non-cyclic change for horizontal force and vertical force on "quiet" days is + 40 and − 18 respectively ; also that the mean excess of absolute value on such days over all days is correspondingly + 34 and − 8 respectively. Thus the relation in both elements is of the same character.

A part of my work consisted of a comparison of diurnal inequalities of the magnetic elements on "quiet" days with those found by including all days (always excepting the excessive magnetic disturbances), and also of a comparison of diurnal range as given : (1) by "quiet" days as observed ; (2) by "quiet" days corrected for non-cyclic change ; and (3) by including all days, in all cases for the different months of the year ; but the work is not sufficiently advanced to enable any particulars to be given.

Dr. Chree, referring to a previous report of the Magnetic Committee and to a paper by Messrs. Robson and Smith in the *Phil. Mag.* for August, 1890, speaks of the differences between diurnal ranges deduced from unrestricted days, that is all days, and from "quiet" days. I may perhaps point out that these comparisons were between "quiet" days at Kew and all days at Greenwich, and were for the element of declination only. In such a comparison the question of difference of locality must be taken into account, and also possibly to some extent the difference of instruments. But in a paper which I communicated to the *Phil. Mag.* for January, 1891, I made a more direct comparison of results, for the one year 1889, comparing the diurnal inequalities for "quiet" days (five in each month) at Greenwich with those for all days at the same place. This comparison was made for all the three elements of declination, horizontal force, and vertical force. The five-day results were not corrected for non-cyclic change, but in declination and vertical force this was evidently small. The results show a marked difference between the diurnal inequalities for "quiet" days and for all days. The later work in this direction, yet incomplete, to which I have above referred, includes a discussion of the diurnal inequalities for the five years 1890 to 1894 for "quiet" days and for all days, and the results seem likely to support those found for the single year 1889.

COMPLETE X-RAY OUTFIT.

The General Electric Company, of 69, Victoria-street, have sent us a copy of a price-list of apparatus required for obtaining X-ray effects. The rapid adoption by medical men of this means of examining the framework of the human body has caused a demand for complete sets of apparatus. So many people totally unversed in the use of electrical apparatus now have to take up the subject, that practical advice both as to the choice and working of the induction coils, batteries, and tubes is of great service. The General Electric Company have



accordingly arranged standard groups of apparatus in which the batteries, coils, and tubes are all mutually suitable. They have also equipped a small laboratory at 88, Queen Victoria-street, where the apparatus can be seen at work and practical instruction given. With each set sold instructions are given, which instructions have been prepared after the experience gained from some months' experimenting. Some two or three kinds of batteries are listed as suitable, and the choice amongst them depends on the local convenience. Where a direct-current supply for charging accumulators is available the portable sets of these secondary batteries are to be preferred, in our opinion, to any primary cells. The tubes supplied by the company are of what they call the King's College pattern, illustrated herewith. It is claimed for these tubes that they are most uniform in their action, and very durable. If these qualities are ensured by care in manufacture and selection the value of the tube is much increased, as nothing is more annoying than to have a tube failing just as an important point in the investigation is reached. The induction coils also repay the extra cost of good manufacture, and we would advise our readers that the best makes are cheapest in the long run. Some half a dozen different sets are listed, and we would suggest that in the larger outfits for hospital use spare tubes should be included.

Presentation.—Mr. George C. Sillar, works manager of the Brush Electrical Engineering Company, Limited, for the past 12 years, was married on October 14, and, to mark their respect and esteem for him, some of his friends and colleagues in the company have celebrated the occasion by presenting him with a carriage-clock. Mr. Sillar has just completed his fifteenth year of service in the Brush Company.

BOUND VOLUMES.

Vol. XVI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE OUTLOOK.—No. 3.

We have in previous issues harped upon a topic which really should be of absorbing interest. One point has not hitherto been touched. It is important, and is playing its part in the volume of business obtained by English firms. When we write English we include Great Britain and Ireland. Whether the business goes to England, Scotland, or Ireland is to a certain extent a matter of indifference; but when it goes to America or Belgium, or France or Germany, we ought to look carefully into the matter. Questions, then, relating to the connection between capital and labour must be considered. It is too late in the day to attempt to teach the principles of economical science to the labouring classes. We have long seen that mankind is moved more by an appeal to the passions than to logical reasoning. Men who think they can obtain an extra couple of shillings a week, or restrict the labour in that particular market to ensure high wages, have no thought nor care about indirect results. To them the only results are the direct results. To reason with such people is labour in vain. Taking advantage of this "human nature in man" is another class—a class that has existed throughout the centuries—and is the most contemptible that ever breathed the free air of heaven. This class panders for its own purpose to the passions and the ignorance of "labour." Verbosely profuse in its promises to relieve the curse of work and suffering, in reality it puts its tongue into its cheek, takes the proceeds of its verbosity, and grows fat and flourishing thereon. Emissaries from competitors in trade are ever ready to add fuel to the flames, and, if possible, to keep up a feeling of distrust between employer and employed. The result in England will prove disastrous—nay, has proved so. With the general question however, we have here nothing further to do, but will restrict our remarks to a special point. The London County Council, which should stand at the head of all municipal bodies as being a model to be followed, is probably of all such bodies the worst. It has been the sport of fads and faddists, but perhaps its worst work has been in connection with the labour question. To obtain cheap popularity, to obtain votes, many of its members have lent themselves to the propaganda of the trades unions. Its specifications contain "labour clauses"—clauses so effectual that the best firms will not tender for work. At least this is the natural conclusion from the report of the last meeting, when a committee reported that "twenty-two firms were asked to tender, of whom six declined the invitation, and five decided thereafter not to do so in consequence of the conditions of contract." Eight only of the twenty-two sent in tenders, and one of these withdrew, declining to abide by these "conditions." Practically this means that somewhere about 70 per cent. of selected firms decline to work under the County Council. If that is not a disgraceful state of things, we know not what constitutes disgrace. Here we see twenty-two high-class firms, whose sole object in life is to do business—and as much of it as they can get—asked by a corporate body having any amount of

Digitized by Google

money at its back to tender for work, and to the extent of 70 per cent. refusing. Common-sense tells us that the question of "How much wages?" is not the point at issue. What cares a firm about "wages" if the amount comes out of the pockets of its employers? A may specify ten pounds a week to B to be paid to labourers. What does B care so long as A pays this amount and also the ordinary profits of B? The firm has, however, not only to guarantee to pay these rates themselves, but also to act as private detectives to see that the raw material they use is also worked at these rates. They have at any time to expose their trading books and wages sheets to public inspection, under the penalties which can be seen below. Now to the electrical question. The London County Council required tenders for the plant to light Blackwall Tunnel. The result of the "conditions of contract" is that the work for the engines and dynamos has been given to Messrs. Laing, Wharton, and Down, and it is divulging no secret to say this firm will probably get the equipment from America. We trust that we are in error on this point, but we are stating the generally accepted notion. If it can be proved that America is more suited to the production of such apparatus than England, we have nothing more to say. Our objection is to the driving work away from this country that can be done as well here as in another country by absurd stipulations and restrictions. To obtain the best article at the lowest price the contractor must be allowed to go to work in his own way. We give the clauses which seem to us the germ of all this evil:

"37. The contractor shall at all times during the continuance of this contract abide by, perform, observe, fulfil, and keep all and singular the stipulations following—that is to say:

"1. The contractor shall pay all workmen (except a reasonably number of legally-bound apprentices) employed by him in and about the execution of this contract or any part thereof, wages and wages for overtime respectively at rates not less than the rates stated or provided for in the third schedule hereto; and for each and every breach by the contractor of this stipulation, and notwithstanding the condonation of any prior or other breach, the contractor shall, on demand, pay to the Council as liquidated damages, and not as a penalty, the sum of £5.

"2. The contractor shall observe, and cause to be observed, by such workmen, hours of labour not greater than the hours of labour stated or provided for in the said third schedule; and for each and every breach by the contractor of this stipulation, and notwithstanding the condonation of any prior or other breach, the contractor shall, on demand, pay to the Council as liquidated damages, and not as a penalty, for each day or week as the case may be in which any such breach shall be committed the sum of 5s. per hour for every hour during which, in each day or week, as the case may be, each such workman shall be employed by the contractor beyond the maximum number of hours stated or provided for in the said third schedule, provided that this stipulation shall not be construed to prohibit overtime, if such overtime be in accordance with the rules of the trade unions concerned.

"3. The contractor shall at all times during the continuance of this contract display and keep displayed upon the site of the works and in every factory, workshop, or place occupied or used by the contractor in or about the execution of this contract, in a position in which the same may be easily read by all workmen employed by the contractor in or about the execution of this contract, a clearly printed or written copy of the third schedule hereto; and for each and every breach by the contractor of this stipulation, and notwithstanding the condonation of any prior or other breach, the contractor shall, on demand, pay to the Council as liquidated damages, and not as a penalty, and for every day during which such breach shall be or continue, the sum of £1.

"4. The contractor shall at any time and from time to time during the continuance of this work, whenever called upon so to do by the clerk for the time being of the Council, produce to such officer or officers of the Council, as the clerk may direct, the time and wages sheets and books of the contractor and all other evidence necessary or proper to show to the satisfaction of such officer or officers whether or not the stipulations contained in this clause have been and are being complied with, and allow such officer or officers to take copies or extracts from such sheets, books, and evidence, or any of them, as such, or officers may deem fit; and for each and every breach by the contractor of this stipulation, and notwithstanding the condonation of any other or prior breach, the contractor shall, on demand, pay to the Council as liquidated damages, and not as a penalty, the sum of £3.

"5. Should any workman or workmen in the employment of the contractor be not paid wages or wages for overtime in accordance with stipulation (1), the Council may pay to any workman or workmen who may have been underpaid the difference between the amount of wages which he or they may have been paid by the contractor and the amount which he would have been paid if the said stipulations had been observed, and may deduct from any moneys due or to become due to the contractor under this contract the amount of the said difference so paid to such workman or workmen."

REVIEWS.

The Elements of Electrochemistry. By MAX LE BLANC, Professor of Chemistry in the University of Leipzig. Translated by W. R. WHITNEY, Instructor of Chemistry in the Massachusetts Institute of Technology of Boston, U.S.A. London: Macmillan and Co., Limited. (Cloth, price 6s.)

Much attention has been given lately to electrochemical processes, and the establishment of what is practically an entirely new theory of electrolysis is still a matter of quite recent history. Indeed, the publication of Van t'Hoff's classic discovery of the position of osmotic pressure in the relations between solutions and gases dates back only to 1887. The whole subject has been worked out on the Continent, not entirely by "eminent Germans" (one of them was a Dutchman and another a Swede), but, at any rate, by men with whom few of those engaged in practical work in England were in touch. It may even yet be doubted whether the new theory will not eventually require addition or modification, but at present it is the standard one. Mr. Whitney's translation of Prof. Le Blanc's work is therefore a book that will be welcome, not only to the student, but to some others past the student stage, whose learning dates back to the dim and distant days of 10 or even 15 years ago. Prof. Le Blanc's book dates from the winter of 1894-95, and is the result of a course of lectures then delivered at Leipzig. It starts with an exposition of the elementary principles of electricity and the C.G.S. units, and a chapter follows mainly devoted to the early history of the galvanic cell. As, however, the reader is expected to be fully conversant with the theory of energy and heat, and have at any rate a general knowledge of the kinetic theory of gases in addition not only to understanding chemical equations (in the old and discarded, as well as the new notation), but also to be acquainted with the difference between *o*, *m*, and *p*-oxybenzoic acid, and to understand what is meant by an isochinolinmethylium ion, it is, to say the least, questionable whether this preliminary knowledge might not just as well have been assumed. But if it is understood that the book is not one to be approached without some previous knowledge, no great harm is done by the rapid revision of what to its readers will be an old tale. In Chapter III. we get to business with the Arrhenius theory of dissociation. As to the difficult question of where the heat comes from necessary for the dissociation into ions, or, put in another way, the energy necessary to separate the positive and negatively charged atoms of the molecule and convert them into free ions, we have the following: "Evidently we have a dissociation differing from that which ammonium chloride undergoes when heated. The parts resulting from the decomposition are electrically charged, and contain equivalent amounts of positive and negative electricity. It is natural to ask: Whence come these sudden charges of electricity? They seem to be produced from nothing. An answer which seems satisfactory is not difficult to give. It is known that metallic potassium and iodine combine to form potassium iodide. In this combination heat is generated, which shows that the two have entered a state in which they contain less

Digitized by Google

energy than before. A certain amount of chemical energy doubtless still remains in the compound, and when the salt is dissolved in water, the greater part of this chemical energy is changed into electrical, through the influence of the solvent. This is the energy seated in the charges of the ions. The potassium ion is positively and the chlorine negatively electrified. By aid of the electric current it is possible to add to these ions the energy in the form of electricity necessary to give them the energy they originally possessed as elements." There are some to whom the explanation in its bare form will be difficult of reception. After the preliminary hypothesis, the book goes straight away in an exposition of the theory of the ions and their migration, and the source of the E.M.F. in a cell. This can hardly be made very easy reading, but the subject is developed as plainly as it can be. There is a valuable chapter on polarisation. In spite of their habit of upsetting established theories with new and better ones, the Germans are curiously conservative, not to say old-fashioned, in many scientific matters, and it may be worth note that the whole of the electrical explanations in the present work are given in the language of the two-fluid theory of electricity. The book throughout is an exposition of theory only. The processes adopted in practical work and the things that happen in them are not mentioned. Mr. Whitney appears to have done his work carefully and well. Some of the letters used to denote electrical quantities are not the ones we are used to in England, and the writing of the limits against the sign of integration is not exactly as we should do it here, but there is nothing of the kind which would cause even a moment's hesitation to the English reader. We have noticed what we presume are two slips in the translation, but they are exceedingly innocent ones, and beyond this there is nothing in the book which would lead a reader who did not consult the title page to suppose that it was not originally written in the English language. Probably that is about the highest praise that can be given to a translation.

A Systematic Course of Geometrical Drawing. By T. A. V. Ford, M.R.C.S.(Eng.), Assistant Master at Haileybury College. London: George Philip and Son, 32, Fleet street, E.C. (Cloth, 3s. 6d.)

Mr. Ford's book is intended to be a text-book for class use, with a sufficient number of graduated exercises necessary for the requirements of draughtsmen or engineering students, the requirements, as is natural, of the army examinations being kept in view. In England, unfortunately, our elementary theoretical geometry is hopelessly divorced from practice, and as a consequence much of our practical geometry consists of a set of directions without the student having any means of knowing the reason of what he does or why his results are correct. Consequently the whole mental value of the study is lost, and, what perhaps may be considered of more immediate importance, when a case arises which does not happen to be exactly provided for in his rote-learned text-book, the student is helpless. If he makes even the smallest deviation from the orthodox way, he does not know whether his result is right or wrong. From this reproach the present work is free. Proofs of almost all of the problems are given. But so curious is the state of opinion as to geometrical teaching that there has to be something like a half apology for this in the preface. "The proofs of the problems, when fairly easy, have been added on account of their mathematical value, and because, when understood, the recollection of the problem becomes more easy." No such apology should have been necessary, but things being as they are, the course adopted is the best possible one under the circumstances. A knowledge of Euclid is, of course, assumed throughout. The range of the book is fairly extensive. In reference to Chapters VIII. and XII. the writer cannot understand the utility of doing slowly and inaccurately, with compass and rule, work which can be done accurately by ordinary computation, or rapidly with a slide rule. But examples of this kind have to be supplied in a complete course. That the geometrical method is not the best way of getting at every result is not the fault of the book. Bearing in mind the object for which it is intended we consider the latter distinctly worthy of commendation. A complementary book on the more advanced branches of geometrical drawing is promised.

THE SUBMARINE TELEGRAPH MEMORIAL.

There has been a number of letters in the *Times* on this subject. First, "Omega," who says: "Those who, unlike Lord Selborne (the chairman at the Winchester House meeting), really know the early history of cable telegraphy know that the true pioneers were such men as Mr. Jacob Brett, Mr. C. V. Walker, Sir Charles Bright, Sir Samuel Canning, and, most celebrated of all though not earliest, Lord Kelvin. It was the demonstrated successes of these pioneers that rendered possible the subsequent financial operations of such men as Sir John Pender and Mr. Cyrus Field." "Omega" finds "an ominous note in the letter which Lord Kelvin addressed to the Marquis of Tweeddale excusing himself from attending the meeting at Winchester House on the 6th instant" (Lord Kelvin has promised to attend a meeting at the end of the month), and concludes by asking, "Is this submarine telegraph memorial going to be a memorial to the growth of submarine telegraphy, or to the greatness of Sir John Pender and of the gentlemen associated with him in the financial development of the cable companies?" Mr. G. R. Neilson, the hon. secretary of the committee, has a letter which practically says the question is an open one: "The whole subject will be fully considered by the Executive Committee at its first meeting, fixed, I may mention, for the end of the month to suit the convenience of Lord Kelvin." How can Lord Kelvin vote on the question of a memorial to himself; or the other people who are still alive? Captain H. A. Moriarty, R.N., C.B., says: "I understand that it has been found desirable to create a memorial to submarine telegraphy, and that the late Sir John Pender, Sir James Anderson, and Cyrus Field have been chosen to represent this highly scientific department. Apart from the humour of the thing, it seems to me that this selection of names is a gross injustice to the real workers in the field," and adds, "to my knowledge Sir James Anderson's only connection with submarine telegraphy, from the technical pioneer point of view, was as captain of the merchant ship 'Great Eastern' when engaged on the laying of the second and third Atlantic cables. There must be many like myself who can testify to the fact that, in the light of an engineering enterprise, Sir Charles Bright and Sir Samuel Canning were the responsible parties, as regards the various early Atlantic cable expeditions of 1857, 1858, 1865, and 1866. Like myself, Lord Kelvin was on board, and should be able to bear me out in this. Many are said to have laid the Atlantic cable, but, in reality, Bright and Canning had the work on their shoulders in the above undertakings." Mr. Henry Clifford ("assistant engineer to Sir C. Bright, first Atlantic cable; assistant engineer to Sir S. Canning, second Atlantic cable") says: "Lord Selborne's address to the committee would lead anyone to suppose that Sir James Anderson had laid the second Atlantic cable. This is an error. Sir Samuel Canning was the engineer in charge of the expedition, and upon him alone rested the responsibility of the undertaking"; and adds that Sir James Anderson was the captain of the "Great Eastern," but in no way responsible for the cable operations. With reference to the first Atlantic cable, Mr. Cyrus Field came over to England to raise the necessary capital, and Sir John Pender acted in a similar capacity in the further extension of submarine telegraphs. But "all the three names pressed forward in the proposed memorial are those of commercial men rather than of engineering pioneers in this great engineering work." Mr. Perry F. Nursey wants the work of Thomas Russell Crampton not to be overlooked, since in 1851 he "succeeded under exceptionally difficult circumstances in laying the first successful cable for a submarine telegraph between Dover and Calais." But Mr. Nursey is hardly serious in suggesting for inclusion in the memorial such a curious list of names as those of Galvani, Volta, Sömmering, Schweigger, Coxe, Romagnès, Oerstadt, Ampère, La Place, Fechner, Alexander, Sturgeon, von Cannstedt, Faraday,

Morse, Gauss, Weber, and Steinheil, "each of whom contributed a round in the ladder which was ascended by Cooke and Wheatstone." What he means to say is that the proper course "is to exclude all personal references and to let the merits of the magnificent system which the memorial is intended to commemorate be the foundation upon which it is reared." Mr. John Temple writes substantially to confirm the letters of Captain Moriarty and Mr. Clifford. As seen above, Mr. Perry F. Nursey suggested that the late Mr. T. R. Crampton "may be regarded as the father of practical submarine telegraphy." In reference to this, Mr. Charles Bright writes: "No single individual can be justly spoken of in that light, as it is a work which has been gradually built up in different directions by many hands. It would, perhaps, be more to the point to refer to Sàlva (1795) as the father of the idea of submarine telegraphy, and to Pasley (1838) as the first to devise and lay an insulated telegraph line under water with good effect. Between these periods Sömmering and Schilling (1812) are said to have exploded mines by subaqueous electric conductors by their own design and arrangements." Mr. Bright adds, "With the last sentence of Mr. Nursey's letter [suggesting the exclusion of all names] all will, no doubt, agree." We have summarised other opinions above—our own will keep.

A COMPLETE TEST OF MODERN AMERICAN TRANSFORMERS OF MODERATE CAPACITY.

BY A. H. FORD, B.Sc.

We have received the bulletin of the University of Wisconsin containing the valuable results of the above test. We abstract the same somewhat fully, so that our readers may compare the results with those obtained by English makers of transformers. The full matter formed the thesis submitted by the author to the university for his bachelor of science degree.

Transformers were obtained from all the leading makers of America, and tested to determine the following data: the copper loss; the iron loss both when the transformer is hot and when it is cold; the division of the iron loss into hysteresis loss and Foucault current loss; the open circuit current; the regulation and magnetic leakage effect; the rise of temperature at full load and no load both if the transformer is in its case and when directly exposed to the air; and, finally, the insulation of the coils. Before proceeding to test the transformers, the author compared the different methods of making the required tests, to ascertain which method was the most accurate. He found that Dr. Sumpner's method was preferable. By this a wattmeter is used first to determine the iron loss at no load. Then the secondary circuit of the transformer is short-circuited through an ammeter, and sufficient voltage applied to the primary circuit to maintain the full-load current. The wattmeter then gives the copper loss together with a small iron loss which is practically negligible. The transformers were tested both at 60 and 125 complete periods per second. The first transformer on the list was an arc lighter transforming to constant current. All the rest were for constant-potential work. Table I. gives the details of the losses and efficiencies of these various transformers, arranged conveniently for reference. Table II. shows the iron losses per pound of iron used, and the maximum induction to which the iron of the respective transformers was subjected. It also gives the total drop of pressure in the secondary between no load and full load, and the proportion of this drop due to magnetic leakage. The author then proceeds to discuss the results of the tests, but with some of his conclusions we cannot agree. Thus, speaking of the iron loss, he says (page 79): "From the results in Table II. it is seen that the magnetic density has a very large effect on the iron loss, the loss per cubic centimetre increasing much faster than the value of B, which would lead one to increase the area of the cross-section of the iron in a transformer core, thus decreasing the value of B. That this is correct is shown by the following computation:

$$H = K B^{1{\cdot}6} = \frac{K N^{1{\cdot}6}}{A^{1{\cdot}6}} = \frac{K N^{1{\cdot}6}}{(V^{2}/_{3})^{1{\cdot}6}} = \frac{K N^{1{\cdot}6}}{V^{1{\cdot}07}}.$$

H is the total hysteresis loss, B is the magnetic density, N is the total number of lines of force, A is the area of a cross-section of the core at right angles to the direction of

the lines of force, V is the volume of the core, and K is a constant. This equation holds for transformers made of the same quality of iron, and having the same shape of core. Consequently, if the winding, and therefore the total core magnetism, of a transformer is fixed, the core losses may be decreased by increasing the volume of the iron in such a way that the magnetic density is proportionately decreased."

The fault in this reasoning is the common fault in all analytical attempts to establish fixed rules for transformer design. The circuits of a transformer are so interdependent that the winding cannot be considered as an invariable, while the dimensions of the iron circuit are varied. The conclusion above would only be accurate if an increase in the dimensions of the iron circuit did not necessitate the use of more copper. In fact, the efficiency of a transformer is not beyond a certain point improved by an increase in the dimensions.

From a comparison of the iron loss in the transformers tested, we see that a test of the iron for its hysteresis loss before it is put into a transformer is a very essential matter if a good transformer is to be made. "The all-day efficiencies given are calculated as though the transformers ran 19 hours on no load and five hours on full load. The total watt-hours' output thus calculated may be taken to approximately represent the number of watt-hours which a transformer is likely to be called upon under rather favourable conditions to deliver in a day where each house or group of houses has a separate transformer. The all-day efficiency equals the total energy (watt-hours) given out by the transformer in 24 hours divided by the energy (watt-hours) given to the transformer in the same time. From a comparison of the all-day efficiencies with the maximum efficiencies we see that the transformer with the least total loss at full load, while it has the greatest maximum efficiency, may not have the greatest all-day efficiency. This consideration shows that it may be of advantage to put many turns of wire in the coils of a transformer, thus increasing the copper loss and reducing the iron loss by making the core smaller and reducing the magnetic density. The number of turns should not be so large as to make the C R drop excessive, or to increase too much the cost of manufacture." The author should also add that the magnetic leakage debars the undue application of this idea.

The leakage drop was determined by deducting the C R drop from the total drop in voltage measured. As the leakage effect is generally small, and is thus found by differences, it is likely to be affected by error of observation. Still, due precautions against error were taken. The drop is seen to be generally less for a frequency of 60 than that for one of 125, which is as it should be. The few cases where the inverse is seen must be put down to errors of observation.

The tests of the temperature rise with the different transformers gave, as might be expected, somewhat discordant results. Still, the following, in the author's opinion, may be taken as a fair average conclusion: For a rise of temperature of 40deg. C. the watts radiated per square inch of core and coils is—with the case on ·21, with the case off ·27, and per square inch of case with the case on ·15 of a watt.

The following are the conclusions drawn by Prof. Dugald C. Jackson on the results of above test:

The complete tables of the results show strikingly that the cheapest transformer is not always the most economical, and that individual tests of each transformer purchased are essential to assure economy. Transformers should be purchased under guarantees of iron loss, regulation, heating, disruptive strength of insulation, and open circuit or exciting current, and every careful electric light superintendent can do no less than test every transformer delivered to him for at least the first two items (iron loss and regulation). These tests are easily made, provided an ordinary wattmeter is at hand.

The guarantees which should be required for transformers are as follow:

1. Iron loss of transformer when operated on circuit at normal pressure never to exceed the values given in the table below for frequencies over 100 periods per second (it may be advisable in some cases to accept a 10 per cent. higher loss for a frequency of 60, in order that the first cost of the transformer for this frequency need not be increased).

2. Drop of secondary pressure due to loading the transformer not to exceed 3 per cent. between no load and full load.

3. Excess of temperature above that of surrounding air at full load after working 10 hours not to exceed 70deg. F. (nearly 40deg. C.).

4. Disruptive strength of insulation between coils and between primary coil and iron, when heated by 10 hours run, to be at least 10 times the primary pressure. Insulation resistance, when heated as above, to be not less than 10 megohms, and guaranteed not to deteriorate with reasonable service.

5. Exciting currents for 1,000-volt transformers not to exceed values given in table when the frequency is above 100. If the frequency is less, the exciting current may be expected to increase as the frequency decreases. In transformers intended for other pressures than 1,000 volts the exciting current may be expected to vary inversely as the pressure. Consequently, if the exciting current of a 1,000-volt transformer is tested by connecting its low-pressure coil to the 100-volt lighting circuits the amperemeter reading may be expected to be 10 times as great as the value given in the following table:

Capacity.	Iron loss.	Exciting current.
1,000 watts	30 watts	·055 ampere.
1,500 watts	40 watts	—
2,000 watts	50 watts	·080 ampere.
2,500 watts	60 watts	—
4,000 watts	80 watts	—
6,500 watts	100 watts	·100 ampere.

For intermediate capacities, intermediate values of the iron loss and exciting current may be expected.

We believe that English makers are prepared to guarantee better results than the above in every detail, except, perhaps, the breakdown pressure. Ten times the primary pressure is a most severe test, and one which we think to be unnecessary. The transformer will never be subject to anything approaching that pressure when at work. It will be noticed from this table of iron loss and exciting current that the professor has a most erratic power factor in his standards, but this is most likely attributable to the printers.

APPLIED ELECTRO-CHEMISTRY.*

BY JAMES SWINBURNE.

LECTURE III.

(Concluded from page 441.)

The anode does not give any serious trouble. Carbon is practically indestructible in fused chloride of sodium, as even hot chlorine has no action on it. If the salt contains any oxygen compounds, such as oxide of sodium, due to combustion of the sodium or sulphate of sodium, a carbon anode will of course be attacked and eaten away. The chlorine that comes off must be kept within some sort of hood, and this gives rise to a new difficulty. Red-hot chlorine, if one may use such an expression, is not at all convenient to handle on a large scale. Perfectly dry chlorine is said not to attack metals, and sodium will keep a bright surface in contact with dry chlorine, but though the chlorine from red-hot salt must be fairly dry it attacks metals at once. No metal can be used as anode in fused salt, for instance, and after it has come off the chlorine will attack, say, an iron hood. Then there is also difficulty in making good contact between the conducting lead and the anode, as the lead, being metal, cannot be in contact with the hot chlorine, and the carbon, on the other hand, must not be exposed to the air. On a large scale it is probable there will also be some difficulty in cooling large quantities of chlorine, as the chlorine must, of course, not be led into the bleach chambers already hot.

The cathode itself of course offers no difficulty. Iron or, perhaps, copper can be used. Sodium, however, floats on fused salt. The surface round the cathode must therefore be covered in, and the sodium either collected and poured off or distilled over. To distil sodium needs a fairly high temperature, which, other things being equal, is a drawback. A still greater

* Cantor lectures delivered before the Society of Arts.

Digitized by Google

drawback is that the sodium does not distil clean, but comes over mixed with salt vapour, and the sodium and salt are condensed together, making a mixture which is difficult to treat.

The chief difficulty as regards the cathode is the hood. Such materials as porcelain are attacked by sodium or sodium vapour, so sodium must not come in contact with them. If iron or copper is employed, as soon as there is a layer of sodium on the top of the salt it makes contact between the cathode and the hood, and the further liberation of sodium is on the outside of the hood, where the metal burns. This not only means waste, but the oxide formed dissolves in the fused salt, and finally burns the carbon anodes. Porcelain hoods have been tried. Many kinds of stoneware or fireclay will stand fused salt well enough; but it does not follow that it will stand in an electrolytic vat. Apparently at the temperature of fused salt it conducts enough to be practically electrolysed. Poincaré gives the conductivity of hot porcelain as about a hundred-thousandth of that of fused salt. It may also be partly attacked by the rather mysterious subchloride of sodium which is supposed to be produced. Such a compound may reduce silicates, just as sodium does. Borchers has proposed or used chamotte, which is, I believe, stoneware made of old fired stoneware, ground up and mixed with new slip and again fired. I do not know what success this material secured. Another proposal is to use porcelain hoods both for the anode and cathode, and to prevent any action by keeping them cool by water circulation. The hood is then coated at all vital points with a casing of cold solid salt, which is an insulator, and protects the porcelain from all attacks on the part of the salt, electrolysis, sodium, or sodium subchloride. Still, the close proximity of melted salt, red-hot sodium, chlorine, and cold water, with nothing but porcelain to separate them, must always be discouraging to a workman whose life is not insured. When all the difficulties so far mentioned have been successfully surmounted, there is still another drawback, and that is that probably there will be no sodium. If a small current density is used no sodium will appear. It was most likely this phenomenon that led the earlier experimenters to suppose that fused electrolytes conducted without decomposition, like metals. What really happens it is very difficult to say. It is generally supposed that the sodium forms a subchloride, but a subchloride of a monad element is a little difficult to believe in. Photographers are on very familiar terms with subhaloids of silver, so we must not be too sceptical about subchlorides of sodium. If the cathode is watched in a cell of fused salt, the liquid appears to be violently disturbed, and luminous red streaks come from the cathode. This looks rather as if sodium was being carried in clouds of small particles into the mass of the salt, and these combined with the salt with evolution of heat. If salt is taken from the neighbourhood of the cathode and cooled, and examined through the microscope, it is found to be full of black specks. On adding water there is effervescence. This looks as if the sodium was not in the form of subchloride, but in little metallic globules. The luminous clouds may be merely clouds of globules of hot sodium, the high temperature being due solely to the enormous current density in the immediate neighbourhood of the cathode. The presence of sodium, or of particles that may be assumed to be sodium, in the cooled salt does not show that they exist at the higher temperature. It is possible that subchloride of sodium exists at the temperature of melted salt, but splits up into normal chloride and sodium on cooling. Lithium if heated in contact with lithium chloride in a closed vessel disappears, apparently forming a subchloride. The subchloride of lithium has even been investigated as regards its fluorescent properties. Chloride of sodium acted upon by cathode rays in a vacuum tube gives off chlorine and turns orange or bluish, and subchloride is said to be formed. Lithium chloride is said to be decomposed in the same way.

It is possible that sodium is not actually deposited against or on the electrode, but in the immediate neighbourhood only. If mercury is used as cathode in a strong solution of a lead salt and a current density is employed, it will be found that lead trees grow on the surface of the mercury. Mercury amalgamates clean lead at an enormous rate—so fast that if you agitate the cathode by touching the cell, trees several inches long will disappear into the mercury so quickly that the eye cannot follow the movement. If the surface of the mercury is watched, it will be seen that the lead is always beginning to form trees, but they are rapidly sucked in by the mercury. It appears as if the lead is not deposited into or really in contact with the mercury, but is thrown down in its immediate neighbourhood, and is then amalgamated by the mercury. If this is the case, it may account for the small yield of sodium from fused salt. It is possible the sodium is deposited in very small globules in the immediate neighbourhood of the cathode, and that a large proportion of it is swept away by the surging salt, and is eventually burnt on the surface of the electrolyte, or turned into salt again at the anode.

The melting point of salt is reduced in practice by adding other chlorides, such as that of calcium, to the bath. Of course, only those chlorides can be used which do not deposit metals more readily than salt. It is quite possible that a little calcium is deposited with the sodium, but it is so difficult to make sodium commercially by this method that an inventor would feel quite encouraged if he obtained any sodium to speak of, even if it were largely contaminated with calcium.

The difficulty, as regards the collection of sodium, has been overcome by Vautin in a very ingenious way. He uses a cathode of fused lead. According to Borchers, whose works are a veritable mine of information, this idea is old, as Rogers deposited sodium into lead and zinc in 1886-89, and published an account of his successful results. Vautin has gone further than this, however. The lead-sodium alloy is in connection with a second vat to which steam is admitted. This takes out the sodium, and if the steam supply is properly regulated pure fused caustic is produced, and has only to be run into drums and sold. This arrangement overcomes a great many of the difficulties inherent in the electrolysis of fused salt. There is no difficulty in collecting the chlorine, as the sodium does not also rise to the top of the vat.

Lead-sodium alloy is available for very many of the purposes for which plain sodium is employed. It would probably not pay to use it for getting aluminium, as the electrolysis and substitution would probably cost more than the simple electrolysis of a cryolite and alumina bath. It is available for the production of cyanides from potassium ferro-cyanides. As sodium has a lower combining weight as well as a lower price than potassium, sodium cyanide is on the whole preferable to potassium cyanide; and it is, I believe, just as good in gold extraction. It must be practically entirely ionised in the very weak solutions used in leaching gold ores, so the metal can hardly make any difference. As potassium cyanide is estimated by its cyanide, the metal being assumed, the use of sodium in the reaction with the prussiate of potash gives a cyanide which tests at over 100 per cent. This has astonished not a few analysts, but is pretty generally understood now.

LECTURE IV.

Electrolytic Caustic and Bleach.

Inventors are still devoting their attention to curious vats and queer diaphragms. In some ways it seems as if too much attention has been given to electrolytic alkali. The alkali business is so enormous that it is a great temptation to inventors, but, on the other hand, the products are low priced, and therefore there is not so much margin. It does not seem to be quite well enough understood that electrolytic alkali is not waiting for some wonderful vat. The processes already in use are quite good enough to give enormous profits if worked economically, but careful supervision is necessary, and great attention to detail. Unfortunately such processes generally get into the hands of limited companies, and limited company management is seldom conducive to success in such cases. It must also be borne in mind that the cost of the electrolysis itself is a small portion of the cost of making electrolytic caustic and bleaching powder. So small a portion of the cost is it that a great improvement in the vats would make very little difference in the price of the finished material. Unfortunately everyone wants to have a vat or system of his own invention. A manufacturer who started up with the determination to use no apparatus which was patented or called after anybody would have a much better chance of success, especially if he employed a few sharp young chemists to watch the vats, make tests, and find out the very best conditions for working. Generally the various inventions consist of varieties of porous diaphragm. Of course an arrangement like that of using mercury as an anode and cathode in one is a different matter. This gives pure caustic, as there is no chlorine in the cathode chamber. If no hydrogen is given off at the surface of the mercury in the anode compartment, the current efficiency must be unity. Having no salt in the caustic means considerable economy in finishing.

Some injustice has been done to this process by those who have raised the cry that the mercury is poisonous. There can be no danger whatever in such a case. I have had charge of lampworks where mercury is used in the exhausting rooms, where it seems to be ubiquitous. Yet all that is needed is to keep the mercury clean, so that it does not flour or powder. When a glass pump breaks, the mercury gets all over the linoleum-covered floor, and is merely swept up. In spite, of this, I have, in several years, never had the slightest case of salivation. When the mercury is permanently under liquid, as in the alkali process, it is quite absurd to suggest danger to the health of the workmen.

One of the difficulties in making bleach is that the anodes are attacked, and a proportion of carbon dioxide is given off with the chlorine. This converts some of the lime into chalk, and lowers the possible percentage of available chlorine. I have found—at least on a small scale—that this difficulty can be overcome by letting the chlorine and carbon dioxide first pass over some bleaching powder, which takes up the dioxide, giving off chlorine instead. When it is converted into chalk it is thrown away. It would be useless to burn it into lime, as it

Digitized by Google

contains chloride as well as carbonate. By this means good bleach can be made. It seemed possible that the carbon dioxide would evolve hypochlorous anhydride, which would be taken up by the lime, giving bleaching powder with a higher percentage of available chlorine than usual. It is doubtful if such a reaction takes place, and still more doubtful if it could be worked on a large scale. Mr. Charles Waite was, however, before me in working out this scheme, and it has been in operation at the Rumford Falls Electrochemical Works for some time now.

Recently, Dr. Hurter has urged that it is impossible to get strong caustic in an ordinary vat at a high current efficiency. I do not understand Dr. Hurter's reasoning, and so I may quite unintentionally misrepresent his views. At a discussion on Mr. Hargreaves's paper, at the Society of Chemical Industry, where I first heard Dr. Hurter's views, I suggested that he was confusing the carriage of the charges by the ions with the liberation of the final products at the electrodes. I have not seen the printed account of this meeting yet, so do not follow Dr. Hurter, but he kindly sent me a paper read by him at the Liverpool Physical Society in 1893. Unfortunately I cannot follow this either, but as far as I can make out Dr. Hurter thinks that in a solution containing salt and caustic the current is carried partly by the hydroxyl ions and partly by the sodium and chlorine ions, with which I agree; and that the portion carried by the hydroxyl, or by the hydroxyl and some of the sodium ions, is useless because it does not make more caustic, with which I disagree entirely. As long as there is available chloride in the immediate neighbourhood of the anode, chlorine and not oxygen will be evolved. At the cathode again hydrogen must be evolved. This being the case either caustic and chlorine are made, or caustic gets at the anode and takes up the chlorine, making hypochlorite and perhaps chlorate.

(*To be continued.*)

LEGAL INTELLIGENCE.

CLAIM FOR ELECTRICAL GOODS.

At the Westminster County Court on Tuesday, before his Honour Judge Lumley Smith, Q.C., the case of Holt *v.* Leonard was heard.

In this case the plaintiff, Mr. George Holt, who described himself as an electrical appliance dealer, of Wardour-street, W., sought to recover a balance of account in respect of six arc lamps supplied to the order of the defendant. The plaintiff's case was that six lamps were supplied, and that four had been paid for, but it was not until months after the goods had been supplied and payment had been repeatedly applied for, that the defendant put forward some excuse about a defect. If the lamps had been in any way wrong witness would have changed them, but he was never asked to do so.

The defendant was called, and admitted that it was not until several months after the delivery of the lamps that he made any complaint; and upon this evidence his Honour gave judgment for the plaintiff, with costs.

COMPANIES' MEETINGS AND REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

The confirmatory meeting for the reduction of the share capital of the Company is to be held at Cannon-street Hotel, E.C., on November 2 at noon. The proceedings at the first meeting have been reported in our columns. A circular has been issued by the secretary of the Company (Mr. Broadhurst), as follows: "For the reasons pointed out in the report recently issued to the shareholders, it has been decided to reduce the Company's capital by writing off £1 from the nominal value of each of the 90,000 ordinary shares. For the benefit of those shareholders who were not present at the meetings of the Company on 5th inst., the directors have desired me to explain the effect of the proposed reduction in greater detail than appeared in the report. Under the constitution of the Company the holders of preference shares have a preference in dividend, but not as regards capital; and therefore, in the event of the Company going into liquidation (a remote contingency), the holders of ordinary shares would be entitled to receive three-fifths and the holders of preference shares two-fifths of any surplus assets, after payment of debentures and other debts and liabilities and the expenses of liquidation. After the capital has been reduced in the manner proposed, the holders of preference and ordinary shares will be entitled to participate in equal shares in the assets on winding up, and neither class of shareholders will be in any way prejudiced as regards dividend. The directors, who hold a large number of ordinary shares themselves, have, after careful consideration, decided that under all the circumstances the proposed mode of reduction is the best available, and wish to point out that, as it will facilitate payment of dividends, the holders of ordinary shares will reap the main benefit of the proposed reduction so long as the Company is a going concern. A reduction of the preference capital would entail an immediate and continuing loss on the holders of preference shares, and would have the effect of transferring part of the dividend to which they are now entitled to the pockets of the holders of ordinary shares. The resolution for reduction was discussed at some length at the meeting of the Company held for the purpose on 5th inst, and was eventually passed by a majority of 42 to 10. In order to obtain the sanction of the Court to the reduction it is desirable to have as many votes as possible recorded at the meeting to be held on November 2." With the circular is enclosed a report of the former meeting, and proxies are asked for.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY.

A meeting of this Company, which is in liquidation, was held last week at Winchester House, E.C., Mr. J. H. Duncan, the receiver and liquidator, presiding.

The **Chairman** said the meeting had been called for the purpose of putting one particular point before those interested in the Company before he closed up the accounts and terminated his office Under a scheme certain bonds were issued to them on the English company, which was the holder of all the founders' shares of the French company. So far, the founders' shares were not in receipt of any dividends. The bonds were now in default, and it would have been possible if the liquidator had not been in the way for any creditor to commence proceedings. He had, therefore, delayed the closing of the accounts and the liquidation to prevent these proceedings being taken. Now, however, the inspector of the Board of Trade wanted to know why he did not close the accounts, and he had, therefore, called them together to ask their assent to continue in office. With regard to the progress of the French company by the French capitalists, he might say that the business in France had been taken in hand in a way that could not have been done on this side. Although numerous difficulties had been encountered, they had paid two dividends, amounting to 5 per cent. on the share capital, in addition to paying 6 per cent. interest on the bonds. The founders' shares did not benefit until 10 per cent. had been paid, and reviewing the general prospects he expressed his opinion that there was reasonable expectation that the founders' shares would in time become valuable. The French company was turning out 150 tons a month.

On the motion of **Mr. Shurmer**, seconded by **Mr. Harman**, a resolution was passed requesting Mr. Duncan to continue in office, subject to the approval of the Board of Trade.

MONTE VIDEO TELEPHONE COMPANY.

The annual general meeting of this Company was held yesterday (Thursday) at Winchester House. The directors recommended a dividend of 4 per cent. on the preference share capital of the Company. The **Chairman** (Mr. H. Ward) stated that during the year a marked improvement had been made in the Company's service by the introduction of a new microphone. Mr. F. W. Jones was re elected director, and Messrs. Gérard Van de Linde and Son were re-elected auditors. The balance-sheet, which was taken as read, shows a balance on the profit and loss account of £838. 4s. 7d. to be carried forward to next year.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY, LIMITED.

The report of the directors of this Company for the half-year ended June 30 last states that the revenue for the half year amounted to £92,071 and the working expenses to £19,210. After providing £3,200 for debenture interest and sinking fund and £1,649 for income tax, there remains a balance of £68,011, to which is added £15,049 brought forward from December 31 last, making a total of £83,060. A quarterly interim dividend, amounting to £19,500, has been paid and £20,000 transferred to the reserve fund. The directors now recommend the declaration of a final dividend of 3s. per share, making with the interim dividends a total dividend of 6 per cent. for the year, and also the payment of a bonus of 2s. per share, both free of income tax, which together will amount to £32,500, leaving a balance of £11,060 to be carried forward. The dividend and bonus will be payable on 29th inst. The receipts for the half-year include the sum of £1 500 dividend to December 31 last on the Company's shares in the African Direct Telegraph Company. The various sections of the Company's lines are in good working order.

The shareholders' meeting is next Wednesday at Winchester House.

EASTERN EXTENSION TELEGRAPH COMPANY.

The report of the directors of the Eastern Extension, Australasia, and China Telegraph Company, Limited, for the half-year ending June 30 states that the gross receipts, including Government subsidies, have amounted during that period to £313,915, against £264,138 for the corresponding half-year of 1895. The working expenses, including £19,917 for cost of repairs to cables and expenses of ships, absorb £87,256, against £95,255 for the corresponding period of 1895, leaving a balance of £226,659. From this is deducted £4,028 for income tax, £20,000 transferred to the

Digitized by Google

fire insurance fund, £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving £170,735 as the net profit for the half-year. Two quarterly interim dividends of 1¼ per cent. each, amounting to £62,500, have been paid for the half-year, leaving £108,235, of which £75,000 has been transferred to the general reserve fund and the balance of £33,235 is carried forward. The working of the Australasian tariff arrangement for the fifth year of guarantee ended April 30 last, resulted in the guaranteed figure being again exceeded. This was due to the heavy gold-mining traffic with Western Australia during the past year. In addition to the revision of the local rates referred to in the last report, and which took effect on July 1 last, the directors have decided to make substantial reductions of tariff between India and China, Japan, etc., to come into force on January 1, 1897. Reductions in most of the Company's through rates were also agreed upon at the International Telegraph Conference recently held at Budapest, several of which will come into force on January 1 next, and the remainder on July 1, 1897. The immediate effect will undoubtedly be a falling off of revenue, but it is hoped that in time the loss will be diminished by increase of business. The long pending negotiations between the Company, its partners in the China traffic—the Great Northern Telegraph Company—and the Chinese Telegraph Administration, for a friendly working arrangement, have at last been brought to a satisfactory conclusion. The arrangement not only restores amicable relations between the Administration and the companies, but settles the troublesome question of exchange, from which the Company has so severely suffered in the past, by enabling it to collect in Chinese currency a fair equivalent for its sterling charges. The agreement was ratified by all the interested Governments on July 31 last, and brought into operation on the following day.

The Marquis of Tweeddale has been appointed chairman, and Mr. F. E. Hesse to the position of manager as well as secretary.

The Company's meeting is at Winchester House on Wednesday next.

HOVE ELECTRIC LIGHTING COMPANY, LIMITED.

The Secretary, in forwarding the notice and warrant for interim dividend, has issued a circular to state that the business of the Company continues to improve satisfactorily. The number of consumers has increased to 305, and the lamps attached to the Company's mains are now equivalent to 20,911 lamps of 8-c.p., while the net revenue for the half-year ending June 30 has increased by nearly 25 per cent. over the amount for the corresponding period of last year. The directors have pleasure in stating that the 5 per cent. debentures were duly paid off on July 1, according to notice, and the loan from the Company's bankers has also been extinguished. The total debentures now issued are £7,300 at 4½ per cent., and £14,600 at 4 per cent. The whole of the share capital of the Company has been subscribed, the last 922 shares at a premium of 10s. per share. The reserve fund now amounts to £1,287. Considerable extensions are being made to the Company's mains to meet the demands of new consumers.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Bucharest.—Tenders will be received at the Mairie, Bucharest, on November 16 for two stand-by steam-engines for a water-power electric generating station at Grozavesti.

Wolverhampton.—Tenders are required for an electric lighting heating and cooking plant for the Victoria Hotel, Wolverhampton. Specification may be seen on application to Mr. Thomas J. Barnett, secretary, 25, Darlington-street, Wolverhampton.

Homburg v. d. Hohe.—The City Authorities of Homburg v. d. Höhe will receive offers up to November 1 for undertaking a concession for the erecting and working an electricity supply station for the city. For particulars application should be made to die Städtische Bauverwaltung, Homburg v. d. Höhe.

Dublin.—The Dublin Bread Company, Limited, invite tenders for a motor van. Particulars, specifications, conditions, and form of tender may be obtained at the office of the consulting engineer, Mr. F. J. Warden-Stevens, A.M.I.E.E., 34, Victoria-street, Westminster, on deposit of £2. 2s., which will be returned on receipt of a bona fide tender.

Werl (Germany).—The Local Authorities propose to submit to tender the construction and maintenance of an electric power and lighting generating station, and also an electric tramway from Werl to Wikede, with an eventual extension to Hamm. Further particulars will be obtainable at the Rathhaus, Werl-i.-Westf., Germany. The date for the tenders is November 3.

Cologne.—Tenders are required by the Municipal Authorities for the construction and working of electric tramways in the city of Cologne to an aggregate length of 20·3 kilometres (12¾ miles). Specifications, plans, and particulars are obtainable for 10 marks (10s.) from der Registrateur B, des Oberbürgermeisteramt, Köln, Germany, and tenders must be in by November 6.

Paris.—Tenders will be received by the Post and Telegraph Authorities at Rue de Grenelle 103, on November 10, for the supply of Baudot telegraphic instruments (five lots), also messengers' wallets (three lots). Application for permission to tender must be made before October 30. On November 20 tenders will be received for the supply of various parts of telegraphic instruments for the next five years. Application must be made before November 10.

Bradford.—The borough electrical engineer is prepared to receive tenders for the following meters—viz., 117 Aron meters, 86 Frager meters, 24 Edison meters, 21 Oulton and Edmondson meters. A list giving details and capacity of the above meters can be had on application to the Electricity Office, Town Hall, Bradford. Tenders are to be endorsed "Tender for Meters," and to be addressed to the Borough Electrical Engineer, Town Hall Bradford. All meters are guaranteed to be in good condition and working order.

Madrid.—The Secretary of State for Foreign Affairs has received a despatch from H.M. Chargé d'Affaires at Madrid stating that a free public competition is announced in the *Gaceta de Madrid* of September 4 for the grant of the contract for the construction and establishment of three submarine cables to join the islands of Luzon, Panay, Negros y Cebu, in the Philippine Archipelago. Tenders must be lodged within 90 days of the publication of the conditions at the Spanish Ministry of the Colonies, accompanied by a deposit of 50,000 pesetas. The particulars received can be seen at the Commercial Department of the Foreign Office between the hours of 11 and 6.

London, W.—The Great Western Railway Company require tenders for the supply from December 1 next to November 30, 1897, of telegraph instruments, telegraph apparatus, copper wire, G.P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, carbons for electric light, telegraph poles, etc. Samples and patterns may be seen at Swindon from 12th to 23rd inst. on application at the office of the Stores Superintendent at Swindon. Specifications, with forms of tender, may be obtained at the offices of the Stores Superintendent at Swindon. Tenders, addressed to Mr. G. K. Mills, secretary, Paddingdon Station, London, and marked outside "Tender for Stores," will be received on or before 26th inst.

Monmouth.—The Town Council invite tenders for (1) machinery (consisting of turbines alternators, steam-engines boilers, electric motors, sewage pumps, etc); (3) cast-iron pumping main; and (4) electric lighting mains. Plans may be seen on application to Messrs. Bramwell and Harris, engineers, 5, Great George-street, Westminster, S W., or to the Town Clerk, Monmouth, from either of whom may be obtained on deposit of £2 2s. (to be returned on receipt of a bona fide tender), a printed form of specification and tender for either contract. Tenders, on the prescribed form, must be delivered with the specification attached (enclosed in a sealed envelope), endorsed "Sewage-Disposal, Tender for Contract No. —," and addressed to Mr. T. R. Oakley, town clerk, Monmouth, by 12 noon on November 2.

London, E.C.—Tenders will be received until 10 a.m. on 26th inst (*a*) for the supply of red fir telegraph poles, to be delivered in London, King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed, for the Postmaster General. The poles to be felled between November 2, 1896, and March 1 1897, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt-sections, from not less than three poles to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender, containing all particulars, may be obtained on application to Mr. Chas. E. Stuart, controller of stores, General Post Office, E C.

Torquay.—The Town Council require tenders for the supply and erection of the following plant: (Section A) boiler-house plant—boilers and fittings, forced-draught apparatus, feed storage, etc; (B) engine house plant—steam alternators, condensers, pumps, steam and exhaust pipes, etc.,; (C) switchboard, etc.; (D) underground mains, lamp-posts, etc.; (E) transformers, etc; (F) meters; (G) accumulators, etc.; (H) crane, etc.; (I) builder. Tenderers are at liberty to tender for any section or sections, but not for part of a section. Specification, with terms and conditions of tender and contract, may be obtained of Mr. W. H. Trentham, consulting engineer to the Council, 39, Victoria-street, Westminster, S.W., or of Mr. Fredk. S. Hex, town clerk, Town Hall, Torquay, on payment of £3. 3s., which sum will be returned on receipt of a bona fide tender. Tenders must be addressed to the Town Clerk, sealed and marked "Tender for Electricity Works," and delivered by 3 p.m. on November 3.

RESULTS OF TENDERS.

Belfast.—The tender of Messrs. Wm. Coates and Son, of Belfast, has been accepted, at £3,210, for supplying a complete electric lighting installation to the asylum, for the Governors of the County Antrim Asylums Board.

Walsall.—The tender of Mr. W. Wistance for putting in the brickwork required for the boiler at the generating station and the foundations of the transformer at St George's Hall, for the sum of £99. 10s., has been accepted by the Town Council.

Bath.—The Corporation have accepted the following contracts: Electric Construction Company, boiler-house plant (Babcock boilers), £2,462, engine-house plant (flywheel alternators), £8,364; Callender's Cable and Construction Company, underground works, (cables), £7,985; Electric Construction Company, converters, £470; Stothert and Pitt, overhead travelling crane, £350—total £19,631. The tenders for the arc lamps and posts are still under consideration.

Digitized by Google

BUSINESS NOTES.

Cheltenham.—Cambray Chapel has been fitted with the electric light.

Howden.—The inhabitants are agitating for a telephone call office to be opened in the town.

Colchester.—Arrangements have been made for lighting the new military hospital with electricity.

Leatherhead.—The General Purposes Committee reported at the meeting of the Urban Council that they had adjourned the electric lighting question for further discussion.

Battersea.—At a meeting of the Vestry a letter was received from Mr. W. D. Young, solicitor, notifying the Queen's assent to an Act confirming the Battersea electric lighting provisional order.

Change of Address.—Messrs. Alex. Shanks and Son, Limited, engineers, have removed their office address from 110, Cannon-street, London, E.C., to Bush-lane House, Bush-lane, Cannon-street.

The Rontgen Rays.—Mr. Edward P. Thompson, of 5, Beekman-street, New York, has received a letter from Dr. Röntgen thanking him for a copy of his book on "X Rays," which he had read with great interest.

London and Lancashire Fire Insurance Company.— The directors have declared an interim dividend of 3s. per share (being at the same rate as the last interim dividend) payable on November 5 1896.

Catalogue.—We have received from Mr. Archibald J. Wright, electrical engineer and manufacturer, 70 Farringdon-road, London, E.C., a comprehensive illustrated price list of electric bells, indicators, batteries, etc.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending October 18 amounted to £1,081, as compared with £1 104 in the corresponding week of the previous year, being a decrease of £23.

New Company.—The Simon Carves By-Product Coke Oven Construction and Working Company, Limited, which has just been registered, also take powers to construct electric works in addition to the works indicated in the title.

Bristol Tramways and Carriage Company, Limited.—The traffic returns for the week ending October 16 were £2,108. 2s. 10d., compared with £2 007. 14s. for the corresponding period of last year, being an increase of £100. 8s. 10d.

The Law Courts, London.—During the Long Vacation the electric light has been fitted up in all the judges' rooms and corridors, and each apartment is now supplied with an electrolier containing the most modern improvements.

York.—The committee who protest against electric lighting by means of municipal capital or under corporation control have issued a circular to each candidate at the ensuing municipal elections asking definitely for his views on the matter.

New Publication.—We have just received from Messrs. Longman and Co. a copy of "Examples in Electrical Engineering," by Samuel Joyce, A.I E.E., which is published at 5s. A fuller notice of this work will appear in a subsequent issue.

West Hartlepool—As a result of the installation of electric driving-plant, and the use of a separate motor to each machine, the coal consumption at Sir William Gray's shipyard is said to have been reduced from 72 tons to 38 tons per week.

St. James's and Pall Mall Electric Light Company.—The sale of electricity for the quarter ending September 29, representing the supply at 6d. per unit, amounted to £10,084, as against £7,402 at the same rate for the corresponding period of 1895.

Bridgwater.—The question of the rearrangement of the lamps in High-street came up at the Town Council meeting and it was stated that that would be held over until they had the report as to the electric light. The new committee would be appointed on November 9.

Rathmines.—The Commissioners have been discussing the advisability of promoting a Bill in Parliament with the object of enabling the municipal body to construct tramways, to purchase existing tramways, to borrow money, etc. The meeting was adjourned till to day (Friday).

City and South London Railway.—The returns for the week ended October 18 were £1,012, compared with £927 for the corresponding period of last year, being an increase of £85. The total receipts for the half-year 1896 were £14,693, compared with £13,701 last year, being an increase of £992.

Newmarket.—At a special meeting of the Urban District Council, held on Wednesday evening, it was agreed to make application to the Board of Trade for a provisional order to supply electricity for public and private purposes in Newmarket. Eight voted for the motion and three against.

Kensington.—The Vestry have agreed to the following applications relative to the extensions of their mains in this parish—viz., Notting Hill Electric Lighting Company, Church-street and Gloucester-walk; House-to-House Electric Supply Company, Cresswell-gardens and Earl's Court-road.

Oldham.—Major-General Crozier has held a Local Government Board enquiry into the application by the Corporation for power to borrow £10,000 for electric light purposes. Additional boilers with condensing plant and special water apparatus and a dynamo will cost £5,000. The buildings will also be doubled in size.

Works Additions.—Messrs. W. H. Willcox and Co. have taken the old works lately occupied by the Sphincter-Grip Company to manufacture their patent wire-bound hose. Formerly all the work had to be carried out in Dublin, but they are compelled, in order to meet the increased demand for this hose, to manufacture it in London.

West India and Panama Telegraph Company.—For the two weeks ended October 15 the receipts were £1,900, as against £2 101 for the corresponding period of 1895. The directors announce, after paying the preference dividends and placing £1,000 to reserve, the payment of a dividend of 1s. 6d. per share on the ordinary shares.

Bingley.—The chairman of the Gas Committee (Mr. J. Gatecliff) has been requested by the District Council to have an interview with Mr. Harris with respect to the proposal of the Leeds and Liverpool Canal Company to supply the district of the Council with electricity and to obtain all the necessary information of the cost of distribution.

Hartlepools Electric Tramways Company, Limited—This Company has been registered, with a capital of £50,000 in £10 shares, to adopt and carry into effect an agreement with the British Electric Traction (Pioneer) Company, Limited, to construct and work the tramways authorised by the Hartlepools Electric Tramways Order, 1895.

Fatal Accident.—Two cable operators from the Anglo-American cable station at Valentia, Ireland, were sailing in a small boat when they were struck by a squall. The boat was capsized and both were thrown into the water. One of them, named George Hutton, was drowned; the other, William Thompson was picked up in an exhausted condition.

Wolverhampton.—At the meeting of the Trades and Labour Council a circular was received from the Wolverhampton branch of the Electrical Trades Union, which numbers about 100 members, expressing a desire to become affiliated with the council. The President said they were very pleased at this and other accessions to the council which had taken place recently.

Folkestone.—The Town Clerk read a letter at the Town Council meeting from Mr. W. G. Hopkins stating that the amendments of Dr. Hopkinson with regard to the electricity scheme affected very materially the whole matter, and asking for a meeting of the committee, and suggesting that Dr. Hopkinson be asked to attend. The town clerk was instructed to call the committee.

Walsall.—The total number of consumers supplied on September 30 last was 65. The wages paid during the month amount to £32. 15s. The value of coal consumed was £20. The electrical engineer has been instructed to obtain tenders for the necessary cable for the transformers, and the Electric Lighting Committee have authorised the chairman to accept such one as he may consider advisable.

Bedminster.—A letter was read at the Parish Council meeting from the Bristol Town Council accepting the Council's terms, with certain restrictions as regarded electric lighting. Mr. Moore said that the latter was rather indefinite, and he did not think much good could be done by discussing it then, and advocated waiting for a definite reply. It was decided that the town clerk be written to for a detailed reply.

Bury St. Edmunds.—The Ratepayers' Association have not yet decided whether they will bring forward one or more candidates for the forthcoming municipal election, but it is thought likely the feeling of the ratepayers will be tested upon the electric lighting question, and that at least one strong opponent of the proposal to apply for a loan to establish public lighting by electricity will seek support at the poll.

Barnes.—At the meeting of the District Council the Finance and General Purposes Committee reported that two representatives from the County of London and Brush Provincial Electric Lighting Company attended before them respecting the Council consenting to a provisional order in the company's favour for this district, when consideration of same was adjourned until next meeting, on November 5 next.

The Mumbles Railway.—The negotiations entered into by a London syndicate to either purchase or take on lease for 21 years the Swansea and Mumbles Railway, with a view to running it by electricity, have been deferred until the end of November. It is stated that on Tuesday, October 27, three members of the syndicate will visit Swansea to further inspect the Mumbles Railway and to confer with Sir John Jones Jenkins.

Aberdeen.—At a meeting of the Watching and Lighting Committee of the Town Council, Bailie Young drew attention to the request for electric street lighting in George-street. It was resolved to hold a special meeting on an early date to consider the whole question of electric lighting of the streets, and specially as to whether lamps suspended from above the centre of the streets are preferable to the standard lamps in use in Union-street.

Burton.—The Lighting Committee have resolved that in the event of the Town Council approving and adopting the resolution of the Public Library Committee for the Burton Institute premises now used as a public library to be lighted with electricity, that Mr. Ramsden cause the necessary mains to be laid in Union-street as far as Duke-street, and thence to the infirmary for that purpose, and for affording a supply of electricity to the infirmary.

Yarmouth.—The surveyor reported at the Town Council meeting that applications had been received for 227 additional lamps for private consumers. The total number was thus increased to 9,279. The income for September amounted to £314. 3s. 4d., and the expenditure to £172. 10s. 11d., a difference of £141. 12s. 5d. The cost of capital and sundry charges was about £130 per month. The Council reduced the price of current for motors and warming to 4d. per unit.

Digitized by Google

Lewes.—Another electric lighting scheme has been placed before the townspeople by Mr. Walker, of London, and it is considered that a good start could be made with £5,000. The estimate of the capital required for laying down the system is £10,000, which includes the provision of 4,000 8-c.p. lamps, together with the upkeep. The details of the estimate were: buildings, £1,500; machinery and plant, £4,000; laying and distributing, £4,000; contingencies, £500.

Cambridge Electric Supply Company, Limited.—The following are the quarterly returns from July 1 to September 30: Number of units sold during quarter 1896, 17,025; corresponding quarter 1895, 13,027. Revenue from electricity supply £467 15s. 10d., as compared with £354. 16s.; revenue from meter rents and other sources £62. 13s. 9d. as compared with £56 last year. The total revenue for the past quarter was £530. 9s. 7d., compared with £410. 16s. for the corresponding period last year.

City and South London Railway Extension.—The engineer for the City and South London Railway extension has submitted for the approval of the London County Council a plan of the proposed station at London Bridge. The contractors have undertaken to carry out the work without demolishing the existing building, which is situated at the corner of Denman-street and Railway-approach. The County Council committee reported the plan to be "sufficiently satisfactory," and recommended it for approval.

Ealing.—The surveyor reported at the District Council meeting that Mr. Drew Bear, one of the churchwardens, and the vicar had expressed themselves very well satisfied with the installation of electric light at St. Matthew's Church. The surveyor further reported that the number of 8 c.p. lamps actually connected with the mains was at present 9,130. He added that during the vacation he had visited a number of public electric light stations, and he thought Ealing had nothing to complain of.

Portsmouth.—It was decided at the Town Council meeting that application be made to the Board of Trade, in the ensuing session, for a provisional order authorising the Corporation to supply electricity within the added areas, and to extend the supply authorised by the Southampton Electric Lighting Order, 1895, to such added areas accordingly. The electrical engineer (Mr. J. H. Lee) was instructed to submit a report and estimate of the cost of fitting the electric light in the municipal buildings and Guildhall.

Swadlincote.—At the meeting of the Urban District Council the Water and Lighting Committee reported that they had offered the gas company £16,000 for the gas undertaking, that being their expert's valuation. In consideration of the company's refusal the committee asked the Council to light the whole district with electricity, and recommended that an expert be employed to take the matter into consideration and give an estimate of the cost. Mr. Mansfield moved the adoption of the report, and it was carried.

Ayr.—At the meeting of the Town Council the burgh electrical engineer reported that the plant and mains still continued to work most satisfactorily. The present maximum demand was 55 amperes, or 10 per cent. above the original rated output of one of the larger sets of plant. Were the town hall to be used before 7 p.m., this would rise to over 60 amperes, which was still 5 amperes below the emergency load at the present rating. The Council have decided to procure a high-speed plant of 200 kilowatts, including cables, etc., at an estimated cost of £5,000.

Darwen.—A meeting of the General Purposes Committee of the Corporation has been held to consider the report of the Electric Lighting Sub-Committee, who deemed it advisable to apply for a provisional order conferring upon the Council the right to manufacture, store, and supply electricity within the area of the borough. However, the General Purposes Committee are not yet satisfied, and after a rather prolonged discussion it was decided to defer consideration of the report until Mr. E. M. Lacey, A.M.I.C.E., should be present and explain several technicalities.

New Deer.—At a meeting of the Lighting Committee it was pointed out that the condition of the existing lanterns was not such as to warrant a continuance of their use. The committee being therefore face to face with the necessity of providing a new system of lighting considered the possibility of introducing the electric light into the village, the water power in the locality being believed to be sufficient for supplying motive power. It was resolved accordingly to communicate at once with some of the electrical firms with a view to procuring all the requisite information.

Shoreditch.—The London County Council have sanctioned the borrowing by the Vestry of £29,665 for the erection of the necessary buildings for a dust destructor and electric lighting station, consisting of a destructor-house, engine house, chimney shaft, battery, test, and pump rooms, offices, stores, and weighbridge, and to obtain the necessary boilers, fans, lifts, hoists, trucks, wagons, and other plant. The period for repayment of the buildings and plant for the dust destructor is limited to 30 and 15 years respectively, the period of 42 years being confined to the cost of the electrical installation.

St. Andrews.—A minute of the Lighting Committee was submitted at the Town Council meeting regarding the electrical lighting of the city. Dean of Guild Rutherford, the convener, stated that he had had a consultation with Mr. Arnot, electrical engineer, Glasgow, whose opinion was that there was not a town in Scotland more favourably situated (being so compactly built) for the introduction of the electric light, and that it could be introduced with great success. Owing to demands on his time at present, however, Mr. Arnot asked that the adoption of the minute might be delayed pending his report.

Ashton-on-Mersey.—At the meeting of the Urban Council, the General Purposes Committee reported that they had met deputations from the Manchester Tramways Company and the Electric Syndicate, and heard the proposed rival plans for laying down tramlines from Stretford to Peel Causeway. The proposals have already been made public, and the committee promised the promoters of both schemes that they would carefully consider them and forward a reply in due course. A letter was read from the Altrincham Electric Supply, Limited, giving notice of their intention to lay electric mains in the township.

Glasgow.—In connection with the new signal-box erected by the North British Railway Company on the bridge at Queen-street Station electric bells have been fitted up from each platform, so that those in charge of the platform can at once communicate with the signalman whenever a train is ready to start, and as to which should have the precedence. The tenth public meeting of the Glasgow and West of Scotland Enginekeepers' Association was held in the city hall a few days ago. Mr. R D. Munroe, M.I.M.E., presided, and in the course of his opening address he spoke of the improvements which had taken place in connection with motorcars and the production of electricity.

Brighton.—The work of extension at the Corporation electricity works is now nearing completion, and the accommodation will be of the most ample description. The additions at the rear include a boiler-house, engine-room, stokery, and storerooms, also messrooms and offices for the overlookers of the various departments. This portion of the work is expected to be finished by the close of the present month The operations in front, which should be completed by the end of November, consist of the addition of two floors, to be used as offices by the manager and the general staff of clerks. Illustrations of the works appeared in our issue of June 26 last. The arc lighting in New-road is being extended.

Manchester.—The following resolution was passed at the meeting of the Manchester Carriage and Tramways Company: "That the scheme for the extension of the company's tramways within the districts of Droylsden, Audenshaw, Swinton and Pendlebury, Moss Side, Stretford, Withington, Sale, Ashton-upon-Mersey, Timperley, Dunham, Altrincham, Bowdon, Hale, and Northenden be approved, and that the directors be authorised to apply in the ensuing session of Parliament for a provisional order empowering the company to construct such tramways, and to work and use the same by horse, electric, or other haulage." The resolution further authorised the borrowing of £125,000 for the purpose.

Appointments Vacant.—The Corporation of Blackpool require the services of a thoroughly capable and experienced electrician to act as mains superintendent. Salary, £2. 10s. per week. Particulars can be seen in our advertising columns.—The Worcester Electricity Committee require an "electrician-in-charge" at their electricity works, to take charge of the running plant and switchboard during an eight-hour shift each day. Applicants must have held a similar position in a high-tension alternating-current station. Salary, £90 per annum. Applications to be sent to Mr. E. T. Ruthven-Murray, city electrical engineer, Guildhall, Worcester, not later than 31st inst. Three recent testimonials are required.

Ludlow.—At the meeting of the Rural District Council the Assessment Committee asked for the Guardians' consent to appear as respondents in the name of the Guardians to an appeal to Quarter Sessions by Mr. J. B. Wood against the rating of his electric light plant, etc., and to make the necessary orders thereon. The clerk read the notice of appeal from Mr. C. B. Cottam (solicitor and agent for Mr. J. B. Wood). Mr. Edwards proposed that the Guardians sanction the defence at Quarter Sessions of the assessment made upon the property of Mr. J. B. Wood, of Henley, in connection with Henley mill and water supply and all buildings and ratable property in connection with the electric light. The motion was carried.

Bray.—Having ascertained that a considerable proportion of the traders and ratepayers are under an erroneous impression as to the nature of the proposed electric tramway line, Messrs. Molloy and Molloy have written to the papers to remove the misconception. The supposition seems to be that the proposed line of tramway is to consist of a double line of rails throughout the length of the main street and Quinsborough-road, but they point out that this is not so. The proposed line is to be single from the town hall terminus to Quinsborough-road, and from Quinsborough-road junction with the main street it will also be single. The rest of the system will only be double where it will not be an interference with the ordinary traffic.

Dundee.—A conference has taken place between ex-Lord Provost Hunter, convener of the Works Committee of Dundee Town Council; Mr. W. Mackison, burgh engineer; and Messrs. Pirie and Moir, directors of the tramway company, along with Mr. Fisher, the manager, with reference to the proposed extension of the tramway system, it having been suggested that powers should be taken under the new Corporation Bill to have extensions effected. The company, it was stated, were disposed to consider the question of the development of the districts named by means of motorcars. The burgh engineer was instructed to provide the tramway company with a plan of the lines proposed, and the probable cost of the various proposals made.

Colwyn Bay.—The surveyor submitted detailed plans, etc., at the District Council meeting of the proposed electric tramway from Colwyn Bay to Llandudno, accompanied by a letter from Messrs. Alfred Dickinson and Co., Birmingham, the engineers. Mr. John Roberts said he would like to see a light railway from Denbigh, through Bettws-y-coed to Colwyn Bay and Llandudno.

Digitized by Google

He thought the County Councils should take that matter up. Mr. W. Davies proposed that the engineers be asked to attend a special meeting of the Council and fully discuss the whole project, and this was agreed to. On the recommendation of the Highways Committee, it was agreed that no steps be taken for the lighting of the new promenade until the cost of lighting the same by gas and electric light be ascertained.

Bath.—At a meeting of the Urban Sanitary Authority, Mr. Alderman Sturges, chairman of the Electric Lighting Committee, brought up a recommendation that the previously sanctioned application to the Local Government Board for permission to borrow £45,000 for electric lighting purposes should be increased to £58,000, the main necessity for the increase being a desire on the part of the committee to provide sufficient capital for a much larger extension of the mains than that contemplated in the original scheme. Mr. Robert Hammond, the consulting engineer of the Corporation, was present, and was called upon to explain the details of the scheme, and after a somewhat warm debate the resolution was carried by 23 votes to 7. The Local Government Board enquiry is fixed for the 30th inst.

Middlesbrough.—At the Town Council meeting Councillor F. Brewster called attention to the minute of the Streets Committee with reference to an application from the tramways company for certain alterations and extensions of the tramway system in order that the whole might be worked by electricity and inviting the members of the Council to inspect the Bristol electric tramway. He said the committee had asked for a plan and detailed explanation of their proposals, but he thought that before putting the tramway company to that expense they should accept their invitation to visit Bristol. The committee's minutes were passed. On Wednesday the members of the Corporation visited Hartlepool, where, by the courtesy of the Hartlepools Tramways Company, they inspected the electric system in vogue in those towns.

Tunbridge Wells.—Mr. A. Boot, the borough electrical engineer, has written to the *Kent and Sussex Courier* calling attention to the fact that the Corporation are now giving a continuous service, "and that pressure is maintained on the mains during the 24 hours. The committee hope that the consumers will endeavour to consume as much electric energy for heating, cooking power, or lighting purposes during the daytime as possible, and thus help them during the hours when it is unprofitable to run owing to the small demand." The meaning is clear, but it might have been more happily put, especially when there are people who are willing, and even anxious, to misunderstand, if by that means electric lighting can be discredited. There appears to be a strong public feeling in favour of lighting St. John's Church with electricity.

Stirling.—Bailie Lawson reported at the meeting of the Police Commission that he had had a conversation with Prof. Kennedy and Mr. Mackenzie, convener of the Edinburgh Lighting Committee, and he thought his committee should be authorised to take Mr. Kennedy's advice as to whether the Commissioners should erect machinery themselves and go on with the manufacture of the electric light, and what prospect of success they might hope to attain. Edinburgh showed an excellence in respect to the electric light which was not surpassed in the United Kingdom. The street lamps, he understood, only cost the ratepayers 2d. per unit. Provost Kinross said he thought the first step was to ascertain what demand there was likely to be for the electric light before incurring the expense of consulting an expert. After some discussion Bailie Lawson's suggestion to consult an expert was adopted.

Ashton.—At the meeting of the Town Council the minutes of a special meeting convened for the purpose of conferring with the directors of the British Electric (Pioneer) Company, Limited, as to the supply, by the Corporation to the company, of electrical energy for the working of the company's tramways were passed. These minutes stated that Mr. Garcke, the managing director, and Mr. Sellon, the engineer of the company, attended the meeting, and a discussion took place as to the terms and conditions upon which the Corporation would be prepared to give, and the company to take, a supply of electrical energy. Mr. Garcke expressed a general approval of the suggestions as to price and minimum supply contained in Mr. Clirehugh's report, and it was ultimately decided that the town clerk, with the assistance of Mr. Clirehugh, should prepare the draft of an agreement between the Corporation and the company, to be submitted for the approval of the committee at a subsequent meeting.

Watford.—At the Urban District Council meeting Mr. Hawtayne's report as to a scheme for electric lighting, which was submitted at a previous meeting, was considered, several questions being asked the engineer, from which it appeared that the scheme would cost something like £20,000. Councillor Benskin said he was opposed to the electric lighting, for he was of the opinion that it would be a burden to the ratepayers. He would be quite satisfied if the matter was deferred for 12 months, rather than add to the rates. He maintained that a matter involving as it did a sum of about £20,000, considering that they had committed themselves to £24,000 for works of sewerage, was worthy of their serious consideration. He felt sure that Mr. Hawtayne in estimating that 8,000 lamps would be taken up the first year was an estimate which could not be understood by the majority of the members of that Board. He proposed that the matter be deferred for 12 months, and eventually this was carried.

Useful Pocket-Books.—We have received a copy of the Electric Construction Company's price list for 1896. It is in pocket-book form, and, besides a mass of information, with prices relative to the company's various well-known manufactures, contains some useful reference tables and matter. Another feature which will make this little book of especial value is the useful character of the memoranda sheets, which are finger indexed and square-ruled. A copy of "The Practical Engineer" pocket-book for 1897 has also come to hand. This useful publication is too well known amongst electrical engineers and others to need a lengthy description of its contents; suffice it to say that the efforts of the proprietors to enlarge its scope and usefulness have in no way relaxed with the present issue. The copy before us includes a diary, and its memoranda sheets are of square ruled paper, which feature, as we have noted before, helps to make these pocket-books of exceeding utility to engineers. The publishers are the Technical Publishing Company, Limited, 31, Whitworth-street, Manchester, and the price, we may add, is 1s. 6d. net.

Newcastle.—Mr. H. Engel has just issued his first circular descriptive of the proposed electrical and general engineering exhibition to be held in this city next year, and to be opened in February next. The Corporation have passed the plans for new and special buildings to be erected on a portion of the Pandon Dene area, at the end of Northumberland-road. Messrs. Armstrong and Knowles are the architects. By the official sanction of the Board of Trade the exhibition will be an international one, and the promoters intend that it shall be the largest show of the kind ever held out of London. The exhibits are expected to illustrate, with some approach to accuracy, the changes and developments that have taken place in electrical engineering and other branches of industry since 1837—the year of the Queen's accession. The exhibits will be classified in two divisions and 14 departments. These departments will be illustrative of electricity, shipbuilding, and sea industries, mining, motorcars, mechanical industries, art furniture, and other products, sanitation, raw materials, alimentary products, horticulture, women's industries, and the fine arts.

Chelmsford.—Messrs. Crompton and Co.'s new works are rapidly approaching completion. The factory will be entirely on the ground floor, which will immensely simplify the working, and will comprise a block of main shops 260ft. by 150ft., shut off from which by iron doors is a store 140ft. by 20ft. The boiler economiser house measures, with the coal-bunkers, 70ft. by 50ft. All the buildings are arranged so that they can be easily extended if required. The water supply will be from tube wells sunk on the site, and there will be a storage reservoir on the ground holding 160,000 gallons. The office block measures 156ft. by 32ft., and is faced with picked stocks and red-brick dressings. The factory buildings were principally designed by Mr. Brunton, the works manager, and the office block by Mr. John Slater, F.R.I.B.A., of 46, Berners-street, London, who also acts as consulting architect for the whole of the work. The contractors are—for the main factory buildings, Mr. J. Bray, of Yarmouth; for the chimney shaft and offices, Mr. Frank Johnson, of Chelmsford; and for the iron and steel work, Messrs. Dorman, Long, and Co. Mr. H. F. Sheppard is clerk of the works.

Croydon.—The Lighting Committee of the Town Council in their report stated that the Electric Light Sub-Committee reported that the British Thomson-Houston Company, Limited, had requested to be allowed to substitute the security of the Comptoir National d'Escompte de Paris in lieu of the guarantee fund as provided for in the contract. The sub-committee suggested that, subject to the execution of a bond to be approved of by the town clerk, the proposed substituted guarantee be accepted, the present moneys in the guaranteed fund to be paid to the contractor less a retention of 10 per cent. The committee recommended accordingly, but it was referred to the Finance Committee. Alderman Barrow asked upon what terms the Council would be prepared to bring the electric light to Park-hill. He knew some of the residents were prepared to take it, and he believed upon certain conditions it would be supplied. Alderman Miller replied that the provisional order provided that if an extension were required in an outside area, consumers, by taking a sufficient amount of current to pay 20 per cent. for three years, would be supplied, but the contractors said that they would be satisfied if sufficient were taken for 10 per cent.

Oxford.—The progress of the electric light during the past year has more than fulfilled the anticipations which were made some 12 months ago. In addition to the 200-h.p. unit of generating plant which was installed in the autumn of last year, the Oxford Electric Company are at present erecting a 600-h.p. engine and dynamo. The horse-power will then be raised from 800 to 1,400. This engine and dynamo will enable the company to add 16,000 lamps of 8 c.p. each to their mains. At this period last year some 14,000 lamps were connected to the company's mains, and to-day there are nearly 19,000. Mains have been laid during the last year in St. Margaret's-road, two extensions in the Banbury-road, Bardwell-road, New Inn Hall-street, Church-street, part of Woodstock-road, Norham-gardens, and Mansfield-road. A new transformer has been placed in High-street, another sub-station has just been equipped in North Parade-avenue for the residential parts of the city, and a third transformer is at present being placed in the vicinity of Carfax. A considerable addition to the public street-lighting has been made; instead of the 16 arc lamps which illuminated High-street and Cornmarket-street, an additional 16 have been added. The candle-power has also been raised from 1,200 c.p. to 2,000 c.p. each.

Wakefield.—At the meeting of the West Riding County Council the General Purposes Committee reported that they had accepted the offer of the City Council to supply electricity to the new offices for all purposes. Alderman Sherwood moved the adoption of the Electric Lighting Committee's minutes at the special meeting of the City Council, and said that everything in connection with the

Digitized by Google

electric lighting scheme was progressing very satisfactorily. Up to the present time, about half a mile of the cable had been laid, and they had excavated about 25ft. down for the chimney shaft. though in the operations they were meeting with more water than was expected, having to take out about 57 000 gallons per hour, which was a very great difficulty. The clerk of the works had informed him that they expected to commence putting in the concrete foundations in a fortnight. The season had undoubtedly been a very wet one, and they had had very great difficulties to contend with at the works. He had been down to them that afternoon, when he learned that the whole of the boilers and everything in connection with the plant could be put down on the spot within a month. The engines, from Leeds, were ready, the foundations were being put in, and in all probability—in fact, he believed without doubt—they would have the electric light by August 1 next.

Cromer.—Mr. Broadhurst had given notice that he would call attention at the Urban District Council meeting to the question of electric lighting for the town, the object of which, he declared, was to induce the Council to obtain, in the ordinary process of procedure, a provisional order for laying down and providing electric light for the town if necessary. At the present moment the inhabitants of the town had to depend on private profit and endeavour for their light and water. Some day the electric light would come there, and unless they took steps it would have to be served in the same manner as they were now served by the gas and water companies. All that he urged was that they (the ratepayers) should occupy the ground and prevent private enterprise entering. If they obtained the order they were not bound to use it. It would, however, prevent someone planting themselves down here, and getting permission from Parliament to cut up their streets, and then charge them for so doing. He moved, "That this Council, in order to protect itself against the advent of an electric light company, decides, subject to the report to be made by the clerk as to cost being satisfactory, to apply for a provisional order." Mr. Spence had very great pleasure in seconding the motion. He thought that it was certainly a step in the right direction. The motion was carried *nem. con.*

Liverpool.—At a recent meeting of the Lighting Committee of the Corporation, it was stated that they had authorised the lighting by electricity of the following streets: London-road, Lime-street, St. George's-place, Ranelagh-street, Parker-street, Clayton-square, Elliot-street, and a portion of Church-street, involving the erection of 43 lamps. The business of the Liverpool Electric Supply Company was transferred to the Corporation on July 1, at which date the equivalent number of 16 c.p. lamps connected with the supply mains was 41,500. Since that date applications had been received for a large number of lamps, and the electric light had been installed in the Municipal Buildings and St. George's Hall, and by the end of this month it was anticipated that the number of lamps connected with the supply mains would reach 48,500. After careful consideration the committee felt justified in reducing the price of electrical energy on October 1 from 7½d. to 7d. per unit, with a special rate of 4d. per unit for power purposes and for very large consumers. Meter rents had also been reduced from 24s to 12s. per annum. The new generating station in Paradise-street was approaching completion, and would be at work in the course of November. It was announced during the meeting that the Board of Trade had approved the system under which electrical energy is to be supplied.

Moss Side.—At the Urban District Council meeting the clerk, Mr. Crofton, read the minutes of a special meeting of the Council held on the 15th inst, from which it appeared that an application made on behalf of the Manchester Carriage and Tramway Company for the Council's sanction to the construction of new tramlines in Upper Chorlton-road and other roads and streets within the Council's district had been declined, "except so far as regarded a single line, with passing places, in Upper Chorlton-road, and in that case only upon certain terms and conditions." At the same meeting it was resolved that the Council should apply to the Board of Trade for a provisional order authorising them to construct and work a single-line tramway along Withington-road, from Brooks's Bar to Raby-street; also along Raby-street and other thoroughfares in the district; and a double line along Princess-road from Bradshaw-street to Claremont-road; and that the tramways company be asked to enter into an agreement as to the lease of the projected lines. It was announced that the Stretford District Council could not undertake to supply electricity outside their own township, but the clerk, Mr. Crofton, stated that he had conferred with the town clerk of Manchester, who was taking steps to insert in a Bill about to be promoted by the Corporation a clause authorising the Corporation to supply electricity to authorities outside the city.

Grimsby.—The Public Lighting Committee have resolved to purchase a new dynamo for the town hall at a cost of about £140. With regard to the provisional order, the Chairman remarked that if they were going to apply again for the provisional order to light Grimsby with electricity, it was time the business was done. The Town Clerk said an application had already been made by a private company, and he had informed them that the Corporation had a provisional order and would oppose them. He thought, however, they might risk letting the order stand over for another year. But if any application were made, he was sure the Local Government Board would say the Corporation had had their chance, and there was no reason why someone else should not come. A private company would come sooner or later, but he thought the risk might be taken another year. Another application had been made as to whether the Corporation would let the order—having their expenses paid and something over. That was an alternative the committee might also consider. It was a pity, he added, to spend more money in this way if they were not going to carry out the order very soon. Mr. Alward cautioned the Corporation and the public against losing another such opportunity as they lost in not having their own gas company. The alternative of farming the order out as the town clerk had suggested would be a bad move. Alderman Evison moved that the matter lay in abeyance for 12 months. Mr. Brown seconded this motion, and it was carried.

Birmingham.—At a meeting of the Public Works Committee the question was discussed whether sanction should be given to the proposed application by the City of Birmingham Tramways Company for a provisional order empowering the construction of certain new tramways. The general proposals of the company have already been described in our columns. Having since their last meeting made an inspection of the routes affected by the proposed order, the committee now decided that they would not recommend the Council to sanction the construction of any tramway along Broad-street, the committee being of opinion that the traffic along the route renders it unsuitable. They also decided that they could not sanction the extension of lines from John Bright-street to Colmore-row by way of Hill-street, but they would raise no objection to a connecting line between the northern and southern routes by way of Suffolk-street, Paradise-street, and Colmore-row. A connection between Colmore-row and the Birchfield and Saltley routes is also contemplated by way of Steelhouse lane. This the committee consider reasonable, provided that Steelhouse-lane is first widened. The substitution of a route to Nechells by way of Dale-end and Coleshill-street for the present horse tramway from Albert-street, along Vauxhall, also met with the approval of the committee; as likewise did a proposal of the company to shorten the route to Molesey by single lines, one outward and the other for return, along Conybere-street and Leopold-street. The Stratford-road route was also generally approved as the one for the experimental installation of overhead electric traction; but the traction question is not affected by the present proposed application for powers, and remains over for subsequent consideration.

Ipswich.—The adoption of an electric lighting scheme at last by the Town Council has produced the usual crop of letters to the local Press to prove that the electric light is always cheaper than gas; that the electric light is always dearer than gas; and that the writer wants to see his name in print. You buy your paper and you take your choice A "Contented Ratepayer" says "let those that are not contented with the present good light, do as Messrs. Cowell, Hodge, Fraser, Footman, and Co. do—instal their own, not try to make those that are quite contented with gas pay for their fads and fancies" Ipswich gas is cheap, but this is the first time the writer has heard it called good. It is understood that "each of the councillors, before going to the meeting, had a note from the Ipswich Gaslight Company stating that those who required electric light could be supplied by the company with gas-engines and dynamos, so that they could instal their own. This tardy conversion to the use of gas for electric lighting comes too late. Several shops, when the old company stopped in Ipswich, put down small gas engines and dynamos rather than be without current. One enterprising pork butcher used a gas-engine he had already there and which in the daytime works a sausage-machine. Curiously enough, his half-dozen or so lamps seem to run more steadily than in many larger installations. Messrs. Gardiner and Co, of Ipswich and Leicester, having tried various forms of gas-burner, write: "We are about to instal a gas-engine and dynamo, for we are assured we can produce the current at 3½d. per unit and thus save 2½d. per unit." They object, and not unreasonably, to some of the more sanguine comparisons between the lighting power of gas and electricity. Messrs. Pretty and Son, on the other hand, say they cannot light their establishment so cheaply with electric light. It really all depends on how you do it, and what figures you bring into the account.

Whitehaven.—The Water and Lighting Committee reported at the Town Council meeting that they had considered correspondence with reference to the Siemens contract, and resolved that, "provided Messrs. Siemens will give another three years' guarantee similar in terms to that contained in the existing contract in respect of the lead-cased cables now being put down by them, the committee will recommend the Council to bear the cost of opening the trenches for the laying of such cables." They had subsequently received a letter from Messrs. Siemens agreeing to accept this proposal. Councillor Musgrave, in moving the confirmation of the minutes, said the matter had been one of very serious anxiety to the committee, inasmuch as the amount involved in the opening of these trenches was no less than £500. The £500 would probably in the end be a capital charge, so that it would not fall heavily on the electric expenditure for the year. The three years' guarantee with the new cable would allow ample time to test it; and at the end of that period Messrs. Siemens would be in the same position as under the original contract—bound to hand over the conductors in thorough working condition. Councillor Musgrave said that while this difference between the Council and Messrs. Siemens had been in course of settlement the work had naturally been at a standstill; but it was intended to relay the whole of the public lighting cable throughout the borough that had not already been relaid. The work would be commenced immediately, if this recommendation of the committee was now passed. The engineer having reported to the Lighting Committee the result of enquiries he had made of occupiers in Duke street and Scotch-street as to the supply of current for private purposes, the committee resolved that a con-

ductor be laid from King-street, up Duke-street to the corner of Queen-street, at an estimated cost of £100.

The South Staffordshire Tramways.—It is stated that a syndicate has been formed to take over the Black Country tramways and work them by electricity. Practically, the Black Country is served by four companies—viz., the South Staffordshire, the Dudley and Stourbridge, the Dudley, Sedgley, and Wolverhampton, and the Birmingham and Midland. The latter, so far as can be ascertained, does not come within the proposed scheme, though the line goes from Dudley to Birmingham, and passes through a good part of the West Midland district of the Black Country. These companies have not been particularly successful, financially, owing to expenses of working and cost of motor power. It is stated that the Dudley, Sedgley, and Wolverhampton Company have consented to dispose of their interests to the syndicate, who propose, in the event of the amalgamation being successful, to adopt overhead electric traction, and to have branches from the main line to Lower Gornal, Gornal Wood, Himley, Kingswinford, and Brierley Hill. It is also proposed to have a tramway laid down between Dudley, Netherton, and Old Hill, and also between the populous districts of Cradley Heath, Brierley Hill, and Dudley. It is thought that the Walsall tramways are not included in the scheme, and no official communication has as yet been received by the West Bromwich Corporation, but it is not likely that the latter body will offer any opposition, except to the electric lighting scheme of the new company, which the Corporation would want in their own hands. These various rumours are exciting a great deal of attention in the towns concerned, and the proposal to adopt electricity as the motive power meets with general approval.

Bradford.—At a meeting of the Corporation Gas and Electricity Committee it was decided to supply electric incandescent lamps to all users free of cost, the conditions being that such lamps should burn for 1,000 hours or have used 60 units during their life. This is equivalent to a reduction of about a farthing per Board of Trade unit to the consumer. The committee agreed to the opening of an exhibition of electrical appliances for cooking, motive power, and lighting in the Swan-arcade, and it was afterwards decided to institute a system of lending motors on hire. The committee further undertook to extend their mains along the Otley-road to Peel Park Hotel. At the Town Council meeting Alderman Joseph Cowgill (chairman of the Tramways, Baths, and Team Labour Committee) moved, and Mr. W. H. Barker seconded, the adoption of the minutes of that committee. From the minutes it appeared that an offer from the Simplex Electric Tramway Conduit Syndicate to work the proposed tramway to Great Horton had been declined. A deputation from the Bradford Tramways and Omnibus Company, Limited, had attended before the committee on the subject of the proposed leasing of suggested new tramways to Bolton and to Great Horton, and after discussion the deputation had promised to send in a tender for the working of such tramways. Mr. J. Hayhurst asked whether any progress had been made in the negotiations with the Bradford Tramways and Omnibus Company Limited, for leasing the proposed new lines, and whether, in the event of the negotiations collapsing, the Tramways Committee intended working the lines themselves. Alderman Cowgill said that the committee had recommended the Council, in the event of the negotiations collapsing, to obtain powers to work the lines themselves. No tender had been received from the tramways company since the interview with the deputation took place.

Messrs. Paterson and Cooper.—The public examination *in re* Paterson and Cooper has taken place before Mr. Registrar Brougham. The debtors—E. J. Paterson and C. F. Cooper—carried on business as electrical engineers, under the style of Paterson and Cooper, at the European Works, Pownall-road, Dalston, 2, Prince's-mansions, 68, Victoria-street, Westminster, and at West Regent-street, Glasgow. The statement of affairs showed liabilities £19,514, of which £9,643 are expected to rank, and the debtors estimate that they have a surplus in assets of £7,021. Mr. Paterson stated that he commenced business as an electrical engineer in 1878, and in 1882 he was joined by Cooper, who introduced £4 500 capital. At that time he had £13 500 standing to his credit. Further sums amounting to £6,600 were paid into the firm's account. During the last 10 years they had been chiefly interested in working patent processes for bleaching and disinfecting by electrolysis. They acquired a half share in the patents by paying £300 or £400 in respect of the fees. Altogether they expended about £12,000 in various ways upon the patents A company was formed to work the English patents, and contracts were entered into by the firm; but, in consequence of the work being pressed on too fast, they incurred a loss of about £5,000 over two contracts. In 1890 the French patents were sold to a French company, and the firm received certain shares, which they subsequently disposed of. They did not consider the firm to be insolvent, but the surplus disclosed in the statement of affairs was subject to the value of the patents. Their present position was entirely due to the delay in selling the patents to a company. Mr. Cooper was also briefly examined. The trustee of the estate, Mr. Edward Cecil Moore, chartered accountant, 3, Crosby-square, London, E.C., is prepared to receive tenders for the purchase of the various businesses. Details and conditions are set out at length in an advertisement in another part of this paper.

Swansea.—A meeting of the shareholders of the tramways company has been held in London, and the chairman, in his introductory speech, remarked that at all the recent meetings reference had been made to the proposed agreement between the company and the Corporation for the sale of the tramways by the former to the latter, and the lease of them by the Corporation to the company for a period of 21 years By the Act of Parliament under which they were working, and under which the tramways were constructed, the Corporation had the power to purchase them at a valuation at the expiry of 21 years from their construction; but in their Act there was a provision that the company should in such a case have the option of a lease for a corresponding period. The first 21 years had not yet expired, but it was thought desirable to anticipate the arrangement by a year or two, as the Corporation were about to obtain powers for electric lighting in the town, including motive power for the electrical working of the tramways. The change from horse traction to electrical power involved considerable expense, wires having to be fixed, motorcars provided, and the lines relaid. Under the proposed agreement the Corporation would defray these expenses with the exception of the motorcars, which would be supplied by the company, and the rent to be paid by the company to the Corporation in future would be based upon the money expended by the Corporation in purchasing the lines and equipping them for electrical traction. The purchase price was to be £32,000 for paying off the £10,400 of 5 per cent. debentures, purchasing motorcars and other purposes, any unexpended balance at the end of three years or earlier being returned to the Corporation, so as to operate in reduction of rent. With regard to rent the company were to pay the Corporation as much interest as the Corporation itself paid for borrowing the money necessary for these works, with the addition of ½ per cent. interest. In addition to that the company had to provide a sinking fund on the £32,000, or as much of that amount as was expended by them, and on any costs which might have to be incurred in widening streets for the purposes of electric traction. These payments had to be calculated on the basis of such an annual sum as would redeem the whole in 30 years, and the money expended by the Corporation in reconstructing and adapting the tramways would have to be paid for by a sinking fund which would clear off these outlays in 21 years. Other clauses provided that the company in its new lease must provide a reasonable service to the satisfaction of the Corporation. On the motion of the Chairman the preliminary agreement was approved, and the directors were empowered to take all the necessary steps for carrying it into effect.

London Lighting Extensions.—The committee of the London County Council have passed a notice, under the Electric Lighting Acts and Orders, from the County of London and Brush Provincial Electric Lighting Company, under the Wandsworth Electric Lighting Order, 1892, of intention to lay mains of high and low tension in Dalebury-road, Beechcroft-road, Brenda-road, Langroyd-road, and Glenburnie-road. The works include mains for extra high-tension current, and among the committee's conditions are: that the dimensions of the street boxes shall in no case exceed 2ft. 6in. square in plan and 2ft. deep; that the mains be laid under the footways wherever it is found practicable to do so; that the low-tension mains be placed 9in. below the underside of the paving and those of high-tension at least a foot lower; that the extra high-tension mains be kept at a distance of not less than 12in. from any other pipe, and be not connected between the stations with any other mains, but do run untapped from station to station; that separate boxes be used for the high and low tension mains respectively, and be kept entirely distinct from one another; that as an additional precaution against accident through defective insulation of the mains, each of the high-tension street boxes be provided with an inner as well as an outer cover, the inner cover being sheathed with wood or other non-conducting material, the two insulated from each other as far as practicable, and the outer cover being efficiently connected to earth; and that adequate means be taken to prevent the accumulation of gas in the boxes and conduits. A notice, dated October 9, 1896, from the same company, under the provisions of the County of London (North) Order, 1892, of intention to lay a low-tension main in Central-street, St. Luke's, was also approved. Five notices were received from the Charing Cross and Strand Electricity Supply Corporation of intention to lay mains (1) in Bow-street and Long-acre; (2) along Great Newport street into Charing Cross-road subway; (3) in Maypole-alley; (4) in James-street, Long-acre; and (5) in Upper St. Martin's-lane, West-street, around a small portion of Cambridge circus and into Charing Cross-road subway; and were approved on the usual conditions. The Notting Hill Electric Lighting Company gave notice of intention to lay mains in Gloucester-walk, and in and across Church-street, and it was approved. The committee also passed, under conditions, three notices from the City of London Electric Lighting Company of intention to lay mains (1) in Stoney-street; (2) along Bankside; (3) across Borough High-street, in Bedale-street, Green Dragon-court, and Montague close. A notice from the House-to-House Electric Light Supply Company of intention to lay high and low tension mains in Cresswell-gardens, and another from the same company of intention to lay low-tension mains in Courtfield-gardens, were passed. The committee have also passed a notice from the Vestry of St. Pancras of intention to lay mains in Francis-street, Tottenham Court-road. Notice was also received of the intention of the Hampstead Vestry to lay mains in Priory-street and Mortimer-crescent. In this case the consent of the County Council is not needed.

The London Tramways Scheme.—Consideration of the report of the Highways Committee of the London County Council, containing the proposal for the immediate sale to the Council of the whole of the undertakings within the county of London of the North Metropolitan and the London Street Tramways Companies, for a subsequent lease to the first-named company of the lines of the two companies, and also of that portion of the undertaking of
